Contents:

1. Reaction scheme
2. Particle compositions
3. Reactivity metrics

The full free radical reaction mechanism initiated by OH abstraction of H from C₃₀H₆₂ has been constructed and validated in previous studies.¹⁻² Scheme S1 sketches out unimolecular and bimolecular routes to the main products: ketones, alcohols, aldehydes and carboxylic acids via several free radical intermediates.

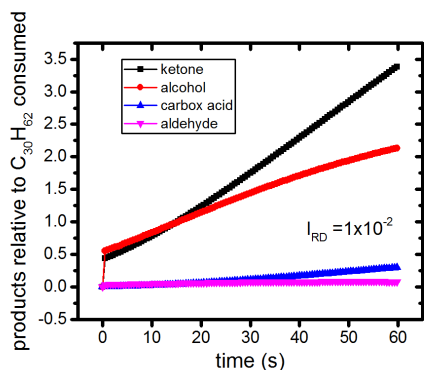

2

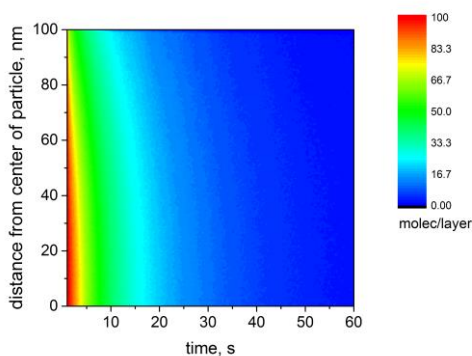

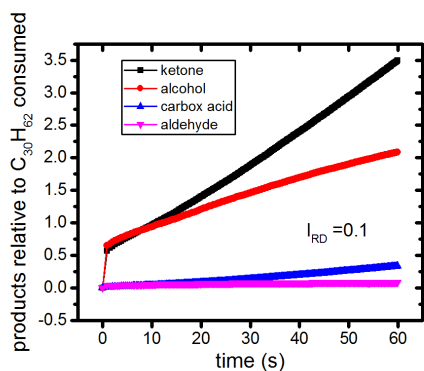

simplifications of the scheme should be noted. The notation “R” is generic and means alkanes or oxygenates of any chain length. Water formed from OH by H abstraction and O_2 from the $RO_2 + RO_2$ reactions are not shown for clarity. Also not shown are the details of acyl peroxy radical disproportionation products from reactions with peroxy radicals with alkyl peroxy or acyl peroxy radicals. The major product of reaction with alkyl peroxy is carboxylic acids and ketones/aldehydes, and the minor product is acyloxy radicals. The product of reaction with acyl peroxy radicals is two acyloxy radicals.

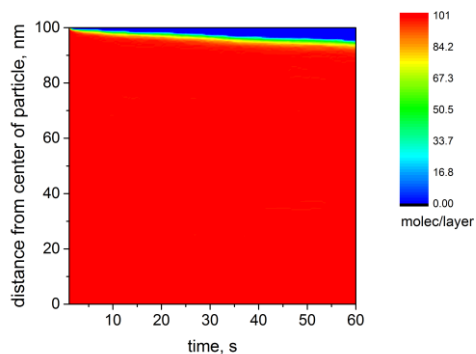

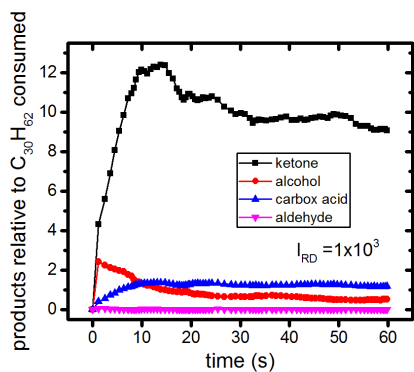

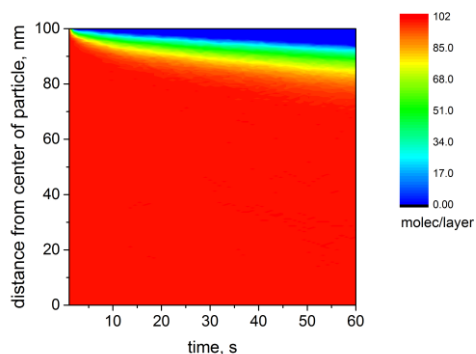

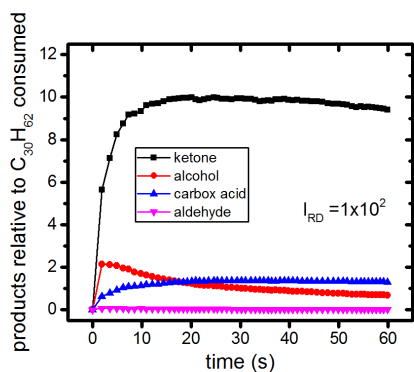

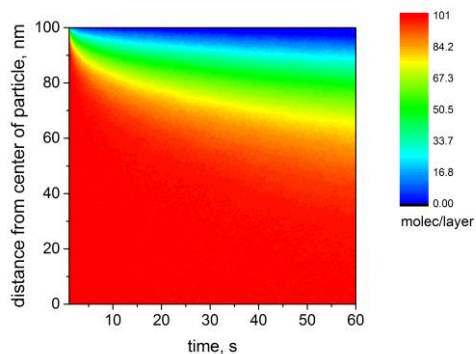

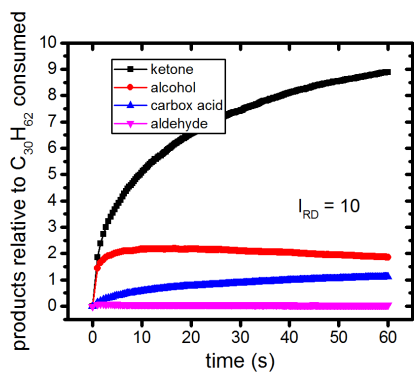

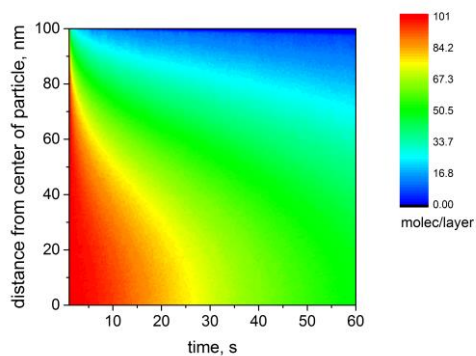

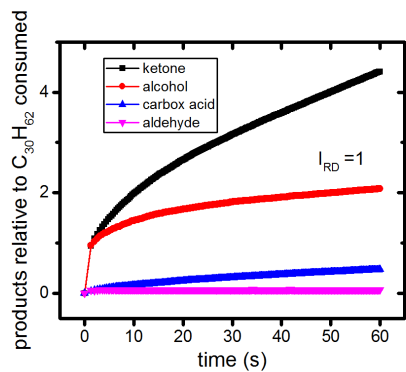

2. Particle compositions

The amounts of functionalities per $C_{30}H_{62}$ reacted and the spatial distribution of unreacted $C_{30}H_{62}$, which shows extent of mixing during oxidation, are presented in Figure S1 as a function of I_{RD} . When $I_{RD} = 1$, the mixing and OH reaction rates are balanced.

This case was calculated
using a single
compartment, no spatial
information is available.

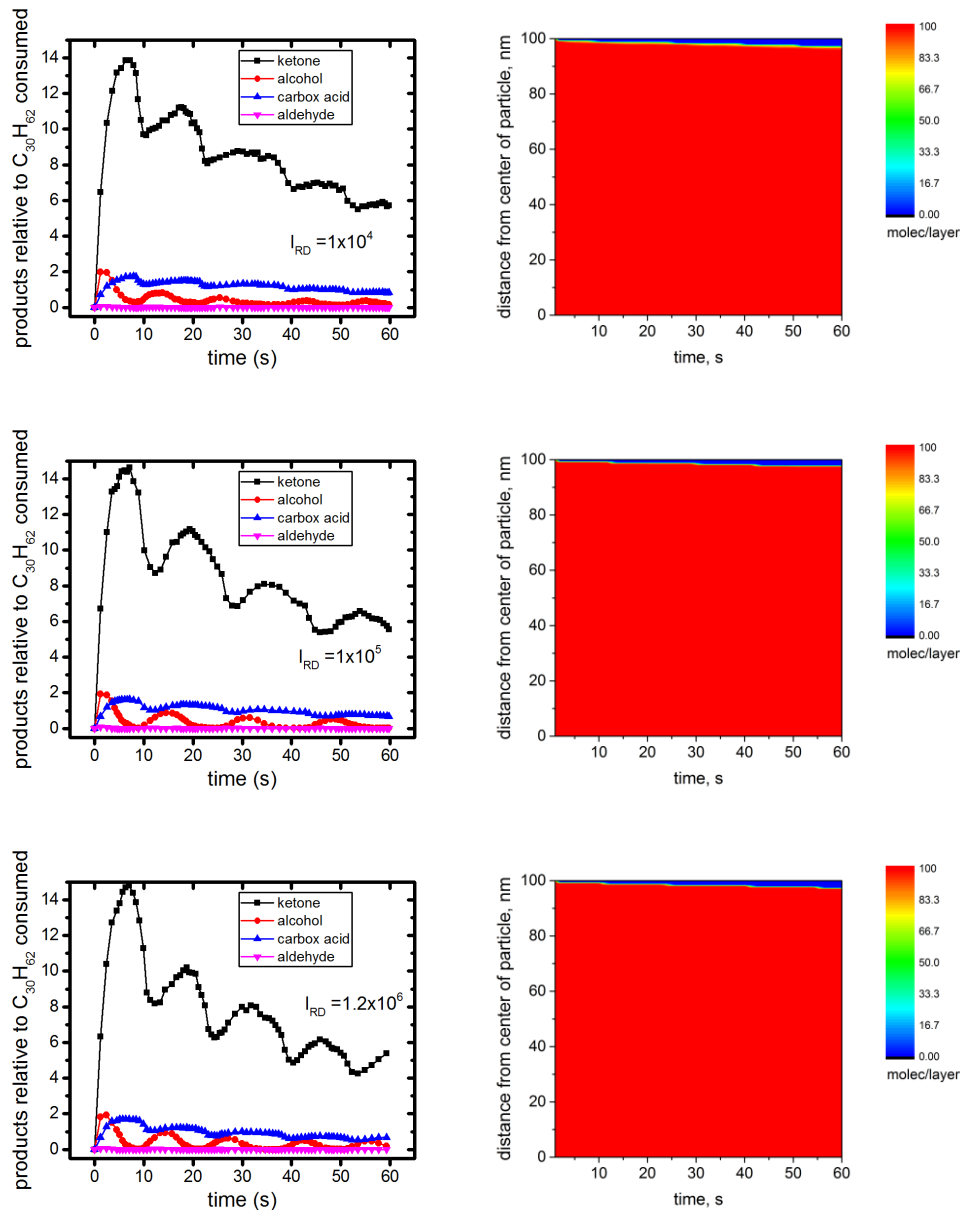

Figure S1. Functionalities formed per $C_{30}H_{62}$ consumed (left column) with corresponding spatial distributions of unreacted $C_{30}H_{62}$ (right column). The spatial distributions reveal the extent of mixing during the reaction, ranging from near-uniform to very little as I_{RD} increases from 10^{-2} to 10^6 , corresponding to self-diffusion coefficients of 10^{-11} to approximately 10^{-18} cm^2/s . The oscillations in the data for $I_{RD} \geq 10^3$ are artifacts of the multilayer simulation. Each 0.5 nm thick layer is assumed to be a well-mixed compartment with no internal diffusion limits on the

availability of $C_{30}H_{62}$ for reaction. Each time a new layer is exposed, the $C_{30}H_{62} - OH$ reaction has the maximum rate. As $C_{30}H_{62}$ is consumed and products evaporate, the rate decreases until a new layer is exposed.

3. Reactivity metrics

Several key measures of reactivity are linked. As D is varied, I_{RD} varies as shown in Equation (5). If I_{RD} is set at a specific value, k_{rx} is calculated from Equation (5). The reacto-diffusion lengths L are calculated using Equation (2). k_{rx} is also plotted in Figure S2.

Table S1. Reactivity metrics calculated for each value of D used in the simulations.

D ($\text{cm}^2 \text{ s}^{-1}$)	I_{RD}	k_{rx} ($\text{cm}^3/\text{molec-s}$)	L (nm) ^a
Well-mixed	$\leq 10^{-2}$	2.01×10^{-12}	14.3
10^{-11}	1.02×10^{-1}	2.09×10^{-12}	4.6
10^{-12}	1.02	2.12×10^{-12}	1.5
10^{-13}	1.02×10^1	2.19×10^{-12}	0.5
10^{-14}	1.02×10^2	2.24×10^{-12}	0.15
10^{-15}	1.02×10^3	2.17×10^{-12}	4.7×10^{-2}
10^{-16}	1.02×10^4	2.10×10^{-12}	1.5×10^{-2}
10^{-17}	1.02×10^5	2.08×10^{-12}	4.6×10^{-3}
8.39×10^{-19}	1.22×10^6	2.10×10^{-12}	1.5×10^{-3}

^a The simulation geometry has a maximum resolution of 0.5 nm, so L values less than this dimension are not directly simulated. Products characteristic of smaller L are inferred from the overall product distributions.

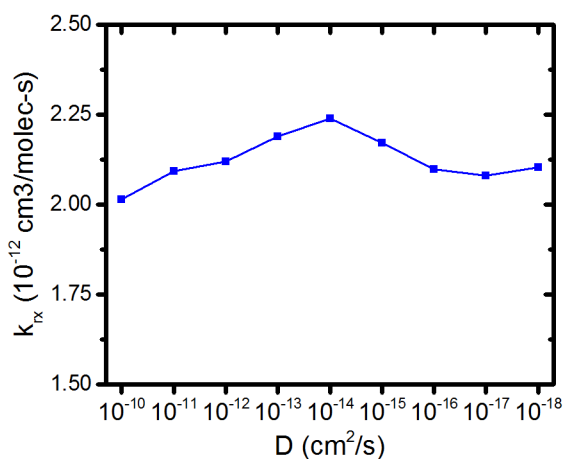

Figure S2. Apparent k_{rx} calculated from Equation (3) for each D in the simulation.
