## 1. General Techniques

All reactions requiring anhydrous conditions were carried out under an atmosphere of argon in flame-dried glassware. Tetrahydrofuran (THF), dichloromethane (DCM), ether ( $\text{Et}_2\text{O}$ ) and ethyl acetate ( $\text{EtOAc}$ ) were obtained from Grubbs' drying stills.<sup>1</sup> MeOH was dried over 4 $\text{\AA}$  MS for at least 24 h. Petrol (petroleum ether) 30–40 °C was used in flash column chromatography. Flash column chromatography was carried out using silica gel (VWR chemicals, BDH) in accordance with Still's method,<sup>2</sup> monitored by thin layer chromatography (TLC) (Merck 60 F<sub>254</sub>) plates. TLC plates were viewed using ultraviolet light ( $\lambda_{\text{max}} = 254/365$  nm) and immersion in  $\text{KMnO}_4$ , anisaldehyde or vanillin stains, followed by heating. Reverse phase HPLC was carried out using Phenomenex - Luna 5u C18(2)100A (column 250 x 10 mm). Except where stated otherwise, commercially available reagents were used as received. “Freshly distilled” refers to distillation over  $\text{CaH}_2$  using a short-path distillation apparatus under a nitrogen atmosphere. Melting points (m.p.) were obtained using an Electrothermal melting point apparatus to the nearest 0.1 °C and are uncorrected. Optical rotations were recorded on a Perkin-Elmer 241 polarimeter, with a path length of 10 cm in  $\text{CHCl}_3$  or MeOH.  $[\alpha]_D^{25}$  values are given in  $10^{-1}$  deg  $\text{cm}^2 \text{ g}^{-1}$ . Concentrations ( $c$ ) are given in grams/cm<sup>3</sup>. Infrared spectra were obtained using a PerkinElmer FT-IR spectrometer (Universal ATR Sampling Accessory), with absorption maxima quoted in wavenumbers (cm<sup>-1</sup>). Peak intensities are described as broad (br), weak (w), medium (m) or strong (s). Nuclear magnetic resonance (<sup>1</sup>H NMR and <sup>13</sup>C NMR) spectra were recorded on Bruker Avance UltraShield AVC 500 and AVX 500 (500 MHz) spectrometers in  $\text{CDCl}_3$ , referenced to residual  $\text{CHCl}_3$  singlet at  $\delta$  7.27 and  $\text{CD}_3\text{OD}$  quintet at  $\delta$  3.31 for <sup>1</sup>H NMR spectra, and to the central line of  $\text{CDCl}_3$  triplet at 77.16 as well as the central line of  $\text{CD}_3\text{OD}$  heptet at 49.0 for <sup>13</sup>C NMR spectra. Chemical shifts are quoted in parts per million (ppm). Coupling constants ( $J$ ) are measured in Hertz (Hz). The splittings are quoted as singlet (s), doublet (d), triplet (t), quartet (q), or multiplet (m). The <sup>13</sup>C NMR peaks were assigned by standard methods using HSQC. Stereochemical assignments were based on NOE studies and X-ray crystallography. Low resolution mass spectra were obtained using electrospray ionization (ESI). High resolution mass spectra were obtained by electrospray ionization (ESI) using tetraoctylammonium bromide or sodium dodecyl sulfate as the lock mass.

#### 4. Optimization of Cross-Electrophile Coupling Conditions

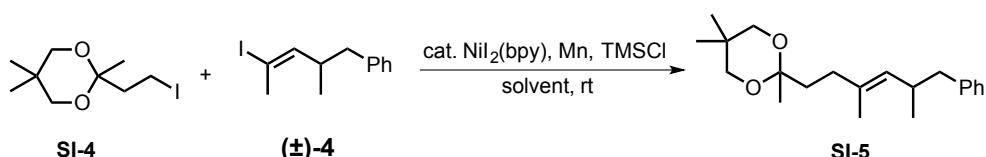

Initial cross-electrophile coupling, between equimolar quantities of TMS-protected alkyl iodide **SI-3** and *E*-alkenyl iodide **4** under the conditions reported by Weix and co-workers for alkyl and alkenyl halides,<sup>13</sup> gave an inseparable 3:1 mixture of **E-26** and **Z-26**<sup>18</sup> in 40% yield (Scheme S1).

**Scheme S1.** Initial cross–electrophile coupling of alkyl iodide **SI-3** and *E*-alkenyl iodide **4**

Optimization of the reaction conditions used alkyl iodide **SI-4**<sup>14</sup> and *E*-alkenyl iodide **4** (Table S1). Under Weix's conditions,<sup>13</sup> equimolar quantities of iodides **SI-4** and **4** gave alkene **SI-5** as a 3:1 *E*-:*Z*-mixture in 70–85% yields (3 runs, Table 1, entry 1), whereas with 2 equiv of alkyl iodide **SI-4**, alkene **SI-5** formed with improved *E*-:*Z*-selectivity (6:1) in 77% yield (entry 2). Alkyl iodide **SI-4** was still consumed if the reaction temperature was lowered from *rt* to  $-20\text{ }^\circ\text{C}$ , or the solvent changed to *N,N*-dimethylacetamide,<sup>13</sup> but only traces of or no alkene **SI-5**, respectively, were observed. However, on changing the solvent to DMF,<sup>19</sup> alkene **SI-5** was obtained with high *E*-:*Z*-selectivity (17:1 □ 20:1) in 86–88% yields (entries 3 and 4).

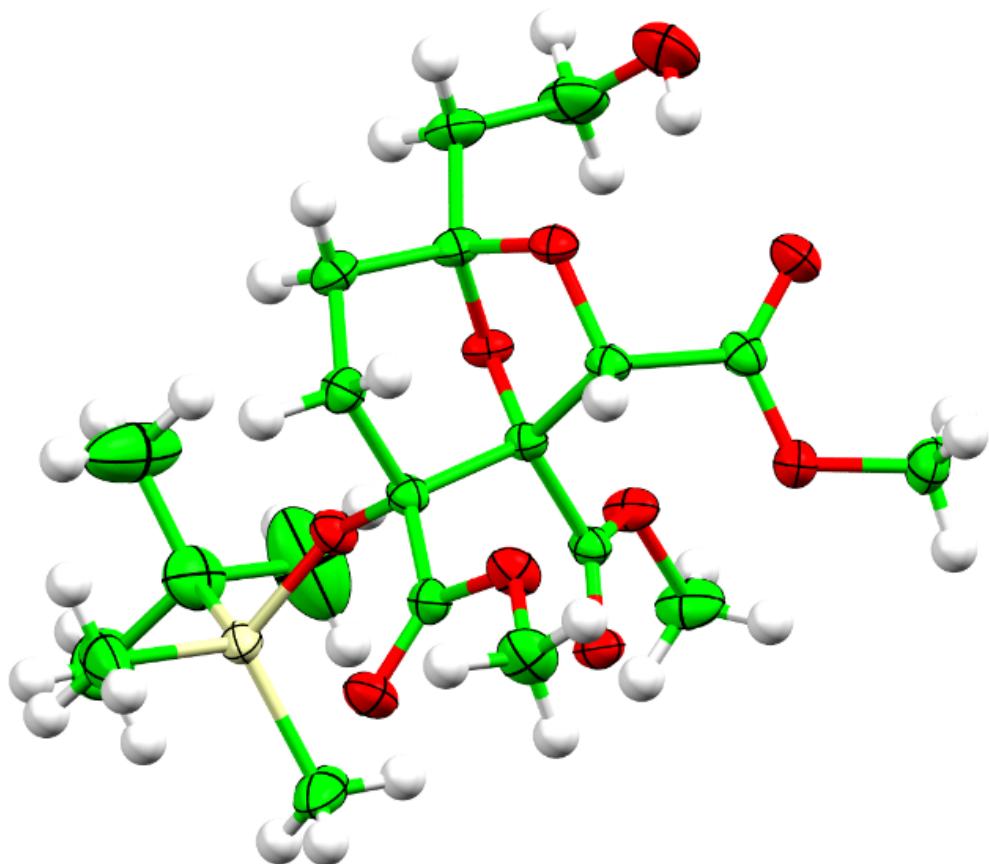

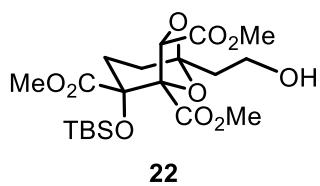

**Table S1.** Effect of reactants ratio and solvent on stereoselectivity (and yield) of alkene **SI-5**.

## 5. Single Crystal X-ray Diffraction Determination

**Fig.1** Crystal structure of **22** with ellipsoids at 50% probability.

Compound **22** was crystallized *via* vapour diffusion by dissolving 5 mg of **22** in ethyl acetate (*c.a.* 50  $\mu\text{L}$ ) and using pentane as the volatile component. Low temperature<sup>20</sup> single crystal X-ray diffraction studies were carried out at 150 K on **22** using  $\text{CuK}\alpha$  radiation on an Oxford Diffraction SuperNova diffractometer equipped with an area detector and graphite monochromator, within the University of Oxford Chemistry

Department. Raw frame data were reduced using CrysAlisPro(Agilent) and the structures were solved using superflip.<sup>21</sup> Full-matrix least-squares refinement of the structures were carried out using CRYSTALS.<sup>22,23</sup> The Flack x parameter<sup>24,26</sup> refined to -0.01(2) and Bayesian analysis of the Bijvoet pairs<sup>26</sup> gave the Hooft y parameter as 0.01(1) and the probability that the structure was the correct hand of >99.99% given that the crystal was enantiopure, thus determining the absolute configuration. Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre (CCDC 1544840) and copies of these data can be obtained free of charge *via* [www.ccdc.cam.ac.uk/data\\_request/cif](http://www.ccdc.cam.ac.uk/data_request/cif).
