Contents

1. Materials and Methods

Nickel(II) chloride (CAS N.O.: 7718-54-9), ammonium molybdate (CAS N.O.: 12054-85-2), urea (CAS N.O.: 57-13-6), boron tribromide (CAS N.O.: 10294-33-4), poly(methylhydrosiloxane) (PMHS, CAS N.O.: 63148-57-2), 1,1'-ferrocenediyl-bis(diphenylphosphine) (DPPF, CAS N.O.: 12150-46-8), tris(dibenzylideneacetone)dipalladium(0) (Pd$_2$(dba)$_3$, CAS N.O.: 51364-51-3), zinc cyanide (CAS N.O.: 557-21-1), MgSO$_4$ (CAS N.O.: 7487-88-9), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, CAS N.O.: 6674-22-2), nickel(II) acetate tetrahydrate (CAS N.O.: 6018-89-9), copper acetate (CAS N.O.: 142-71-2), *N*-methyl-2-pyrrolidone (CAS N.O.: 68-12-2) and ethylene glycol (CAS N.O.: 107-21-1) were purchased form Sigma Aldrich. Methanol (CAS N.O.: 67-56-1), dichloromethane (CAS N.O.: 75-09-2), acetone (CAS N.O.: 67-64-1), *N, N*-dimethylacetamide (CAS N.O.: 127-19-5), and ethyl acetate (CAS N.O.: 141-78-6) were purchased from BDH Chemicals. Compounds 4,5-dimethoxyphthalodinitrile,[S1] 2,3-dibromo-6,7-dipropoxynaphthalene[S2] were synthesized according to the literature procedures. The yields were given as isolated yields. NMR spectra were recorded on a Bruker 600 MHz NMR spectrometer. The chemical shifts (δ) were expressed in ppm with internal standard tetramethylsilane (TMS) and solvent signals as internal references, and *J* values were given in Hz. Standard abbreviations indicating multiplicity were used as follows: s (singlet), br (broad), d (doublet), t (triplet), q (quartet), m (multiplet).

Scanning Electron Microscopy (SEM) and Energy Dispersive X-ray Spectroscopy (EDX) were performed using a Hitachi TM3000 SEM (Tokyo, Japan) equipped for X-ray microanalysis with a Bruker Edax light element Si(Li) detector (Billerica, MA). Transmission electron microscopy was carried out at a Tecnai F20ST FEG TEM instrument. Powder X-ray diffraction (PXRD) measurements were performed with a Rigaku sixth generation MiniFlex X-ray diffractometer with a 600 W (40 kV, 15 mA) CuKα (α = 1.54 Å) radiation source. Nitrogen adsorption experiments were performed with ASAP Plus 2020 (Mircromeritics, Norcross, Georgia) instrument. Elemental analyses were performed by *Atlantic Microlab, inc*. X-ray photoelectron spectroscopy experiments were conducted on a Physical Electronics Versaprobe II X-ray Photoelectron Spectrometer under ultrahigh vacuum (base pressure 10^{-10} mbar). The measurement chamber was equipped with a monochromatic Al (Kα) X-ray source. Both survey and high-resolution spectra were obtained using a beam diameter of 200 μm.

2. Synthesis of Phthalocyanine Based MOFs

2.1. Synthesis of (2,3,9,10,16,17,23,24-octahydroxyphthalocyaninato) nickel(II) NiPc
Synthesis of (2,3,9,10,16,17,23,24-octamethoxyphthalocyaninato) Ni(II). 4,5-Dimethoxyphthalodinitrile (5.0 g, 26.6 mmol), urea (1.6 g, 26.6 mmol), NiCl$_2$ (907 mg, 7 mmol), and ammonium molybdate (300 mg, 0.25 mmol) were refluxed in 100 mL of ethylene glycol under argon atmosphere for 4 days. The mixture was then cooled to room temperature, and 70 mL of water was added. The resulting solid was washed successively with methanol (40 mL × 5) and acetone (40 mL × 5) by using a centrifuge to collect precipitate. The product was then dried under vacuum to give (2,3,9,10,16,17,23,24-octamethoxyphthalocyaninato) Ni(II) as a dark green solid in 65% yield (3.52 g). The characterization data are consistent with literature.[S3]
Synthesis of NiPc. (2,3,9,10,16,17,23,24-octamethoxyphthalocyaninato) Ni(II) (1.2 g, 14.76 mmol) was suspended in 50 mL of dichloromethane, and BBr$_3$ (5.7 mL, 59 mmol, 40 e.q.) was added under N$_2$. The mixture was stirred for 6 days, and then poured into 100 mL of H$_2$O. The precipitate was collected by centrifugation. The obtained solid was then dispersed in MeOH (20 mL), shaken vigorously and then centrifuged. The solid was collected and then subjected by MeOH washing using centrifuge for another 4 times. The product was then dried under vacuum to give **NiPc** as a dark green solid (0.78 g, yield 75%). M.P.: > 300 ºC; ^{1}H NMR (600 M, DMSO-d$_6$): δ = 8.54 (s, 8H), 10.31 (br, 8H).
Figure S1. ^{1}H NMR (600 M, 298 K, DMSO-d_6) spectrum of NiPc.

2.2. Synthesis of (3,4,12,13,21,22,30,31-octahydroxynaphthalocyaninato) nickel(II) NiNPc

R= propyl

Synthesis of 6,7-dimethoxynaphthalene-2,3-dicarbonitrile. A 100 mL two-neck round-bottom flask was charged with 8.04 g (20 mmol) of dibromo-6,7-dipropoxynaphthalene in DMAC (40 mL) and PMHS (400 mg) was added at r.t. The reaction mixture was heated to 120 ºC and Pd$_2$ (dba)$_3$ (366 mg, 2 mol%) and DPPF (300 mg, 2.7 mol%) were added. Afterwards, Zn(CN)$_2$ (3.2 g, 24.8 mmol) was added in 4 portions within 5 hours. The reaction mixture was heated for another 2 hours and then cooled down to room temperature, diluted with EtOAc and filtered. Filtrate was washed with H$_2$O, dried with MgSO$_4$, and concentrated in vacuo. The crude product was recrystallized from an EtOAc/hexane (v/v=1/1) solvent to give colorless crystals (4.8 g, yield 81%). M.P.: 199-201 ºC; ^{1}H NMR (600 M, CDCl$_3$): δ = 7.94 (s, 1H), 7.00 (s, 1H), 3.97 (t, J = 6.5 Hz, 2H), 1.80 (h, J = 7.1 Hz, 2H), 0.96 (t, J = 7.4 Hz, 3H); ^{13}C NMR (150 MHz, CDCl$_3$): δ = 153.0, 133.3, 129.8, 116.5, 107.9, 107.3, 70.7, 22.3, 10.5. HRMS (ESI): m/z calcd for C$_{18}$H$_{19}$N$_2$O$_2$: 295.1447; found: 295.1448 [M+H]$^+$.

Figure S3. ^{13}C NMR (150 M, 298 K, CDCl$_3$) spectrum of 6,7-dimethoxynaphthalene-2,3-dicarbonitrile.

Synthesis of (3,4,12,13,21,22,30,31-octapropyl-2,3-naphthalocyaninato) nickel(II). To a solution of 6,7-dipropoxynaphthalene-2,3-dicarbonitrile (3.82 g, 13 mmol) in DMAC (20 mL) was added NiCl$_2$ (840 mg, 0.3 mmol, 0.5 eq.) and DBU (198 mg, 1.3 mmol). The mixture was then stirred at 180 °C under nitrogen for 3 days. After cooling to rt, the mixture was poured into water. The precipitate was collected by filtration. It was subsequently washed with methanol (10 mL × 5) and acetone (10 mL × 5) by using a centrifuge and then dried in vacuo, which finally gave a green solid as the product (2.81 g, yield 70%). M.P.: > 300 °C; ^{1}H NMR (600 M, DMSO-d_6): δ = 8.22 (s, 8H), 7.67 (s, 8H), 4.11 (t, J = 6.4 Hz, 17H), 1.91 – 1.74 (m, 17H), 1.04 (t, J = 7.3 Hz, 26H) ; ^{13}C NMR (150 MHz, DMSO-d_6): δ = 169.70, 151.37, 131.82, 127.37, 122.69, 110.11, 70.19, 22.35, 10.85. HRMS (ESI): m/z calcd for C$_{72}$H$_{72}$N$_8$NiO$_8$: 1234.4827; found: 1234.4851 [M]$^+$.

Figure S4. ^{1}H NMR (600 M, 298 K, DMSO-d_6) spectrum of (3,4,12,13,21,22,30,31-octapropyl-2,3-naphthalocyaninato) nickel(II).
Figure S5. ^{13}C NMR (150 M, 298 K, DMSO-d_6) spectrum of (3,4,12,13,21,22,30,31-octapropyl-2,3-naphthalocyaninato) nickel(II).
Synthesis of NiNPc. (3,4,12,13,21,22,30,31-octamethoxynaphthalocyaninato) Ni(II) (0.96 g, 0.78 mmol) was suspended in 50 mL of dichloromethane, and BBr$_3$ (3.0 mL, 31 mmol, 40 e.q.) was added. After the mixture was stirred for 5 days under N$_2$, 10 mL of methanol was added. The precipitate was collect by filtration, washed by methanol (20 mL × 6) by using a centrifuge and dried in vacuum to give **NiNPc** as a green solid (0.61 g, yield 87%). M.P.: > 300 ºC; ^1H NMR (600 M, DMSO-d_6): δ = 10.25 (s, 8H), 8.11 (s, 8H), 7.43 (s, 8H); ^{13}C NMR (150 MHz, DMSO-d_6) δ = 169.8, 150.0, 131.5, 126.5, 122.4, 112.7; HRMS (TOF): m/z calcd for C$_{48}$H$_{24}$N$_8$NiO$_8$: 898.1071; found: 898.1089 [M]$^+$.

2.3. Synthesis of NiPc-M (M=Ni, Cu) MOF

Synthesis of NiPc-Ni. To a 50 mL round bottom flask charged with **NiPc** (70 mg, 0.1 mmol), 12 mL of H_2O was added. The mixture was sonicated for 3 minutes to get a dark green suspension. Then 62.2 mg of $Ni(OAc)_2 \cdot 4H_2O$ (2.5 e.q.) and 1.2 mL of $NH_3 \cdot H_2O$ (25%~28%) were added (2.5 e.q.) successively. The mixture was sonicated for another 5 minutes and then was heated at 85°C for 24 hours with the flask loosely capped to permit exposure to air. After that the reaction was cooled to room temperature and the dark blue to black precipitate was filtered. The product was washed successively with DMSO/$NH_3 \cdot H_2O$ (v/v=10:1, 3×10 mL), deionized water (5 × 20 mL), and acetone (5 × 20 mL). The filtrate was then transferred to a vacuum (20 mTorr) oven at 65°C and kept for 24 hours which gave **NiPc-Ni** as black solid (92 mg). The yield was 112% based on a theoretical formula of $(\textbf{NiPc})_1Ni_2$.

Synthesis of NiPc-Cu. To a 50 mL round bottom flask charged with **NiPc** (70 mg, 0.1 mmol), 12 mL of DMSO were added. The mixture was sonicated for 3 minutes to get a clear dark green solution. Then 45.4 mg of copper acetate was added (2.5 e.q.). The mixture was sonicated for another 5 minutes and then was heated at 85°C for 48 hours with the flask loosely capped. After that the reaction was cooled to room temperature and the dark blue to black precipitate was filtered. The product was washed successively with DMSO (3×10 mL), deionized water (5 × 20 mL), and acetone (5 × 20 mL). The filtrate was then transferred to a vacuum (20 mTorr) oven at 65°C and kept for 24 hours, which gave **NiPc-Cu** as black solid (65 mg). The yield was 83% based on a theoretical formula of $(\textbf{NiPc})_1Cu_2$.

2.4. Synthesis of NiNPc-M (M=Ni, Cu) MOFs

Synthesis of NiNPc-Ni. To a 50 mL round bottom flask charged with **NiNPc** (90 mg, 0.1 mmol), 6.6 mL of NMP and 6.6 mL of H_2O were added. The mixture was sonicated 15 minutes to get a homogeneous solution. Then 62.2 mg of $Ni(OAc)_2 \cdot 4H_2O$ was added (2.5 e.q.). The mixture was sonicated for another 5 minutes and then was heated at 85°C for 72 hours with the flask loosely capped. After that the reaction was cooled to room temperature and the dark blue precipitate was filtered. The product was washed successively with NMP/H_2O (v/v=1:1, 3×10 mL), deionized water (5 × 20 mL) and acetone (5 × 20 mL). The filtrate was then transferred to a vacuum (20 mTorr) oven at 65°C and dried for 24 hours, which gave **NiNPc-Ni** as dark blue solid (88 mg). The yield was 86% based on a theoretical formula of $(\text{NiNPc})_1\text{Ni}_2$.

Synthesis of NiNPc-Cu. To a 50 mL round bottom flask charged with **NiNPc** (90 mg, 0.1 mmol), 6.6 mL of NMP and 6.6 mL of H_2O were added. The mixture was sonicated 15 minutes to get a homogeneous solution. Then 45.4 mg of copper acetate was added (2.5 e.q.). The mixture was sonicated for another 5 minutes and then was heated at 85°C for 72 hours with the flask loosely capped. After that the reaction was cooled to room temperature and the dark blue to black precipitate was filtered. The product was washed successively with NMP/H_2O (v/v=1:1, 3×10 mL), deionized water (3 × 20 mL), and acetone (5 × 20 mL). The filtrate was then transferred to a vacuum (20 mTorr) oven at 65°C and dried for 24 hours, which gave **NiNPc-Cu** as black solid (98 mg). The yield was 95% based on a theoretical formula of $(\text{NiNPc})_1\text{Cu}_2$.

3. ATR-FTIR Spectroscopy

Infrared spectra were collected using a JASCO model FT IR-6100 Fourier transform infrared spectrophotometer.
Figure S8. Comparison of ATR-FTIR spectra of **NiPc**, **NiPc-Cu** and **NiPc-Ni**.
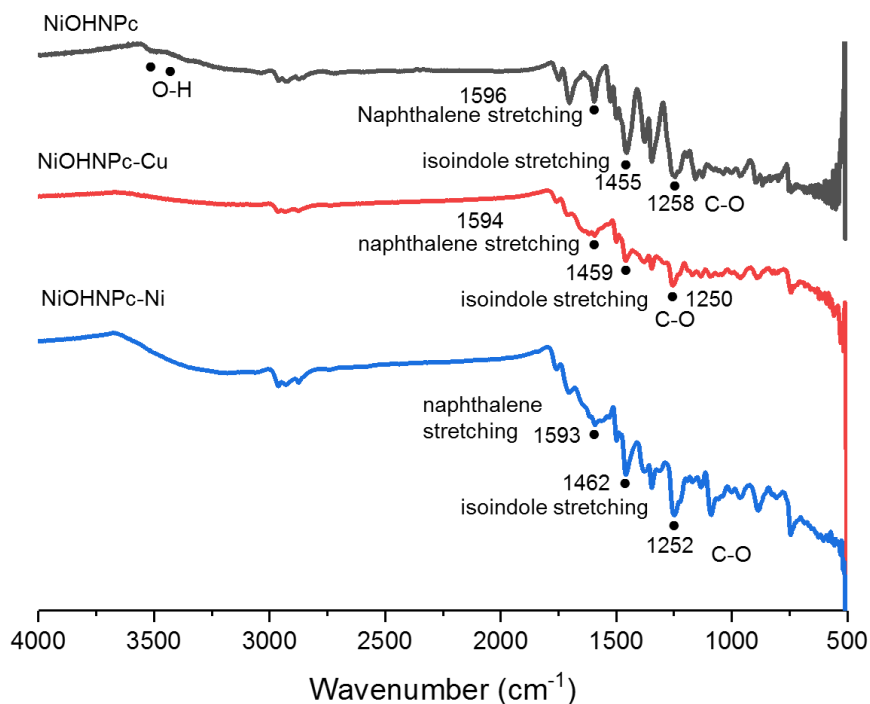

Figure S9. Comparison of ATR-FTIR spectra of **NiNPc**, **NiNPc-Cu** and **NiNPc-Ni**.

4. X-ray Photoelectron Spectroscopy

X-ray photoelectron spectroscopy (XPS) experiments were conducted on a Physical Electronics Versaprobe II X-ray Photoelectron Spectrometer under ultrahigh vacuum (base pressure 10^{-10} mbar). The measurement chamber was equipped with a monochromatic Al (Kα) X-ray source. Both survey and high-resolution spectra were obtained using a beam diameter of 200 μm. The spectra were processed with CasaXPS.

Figure S10. XPS survey spectrum of **NiPc-Ni** showing the presence of C, N, O, and Ni elements.

Figure S11. Deconvoluted XPS spectra of the **NiPc-Ni**: (a) N1s, (b) O1s, and (c) Ni2p. The black, grey, and green curve represent original data, background and the sum of the deconvoluted peaks, respectively. In (a) the blue curve corresponds to N(1s) in C=N···Ni and the red curve corresponds to C1s C=N-C. In (b) the red curve corresponds C-O and the blue curve corresponds to C=O.

In (a) the blue curve corresponds to N(1s) in C=N···Ni and the red curve corresponds to C1s C=N-C. In (b) the red curve corresponds C-O and the blue curve corresponds to C=O.
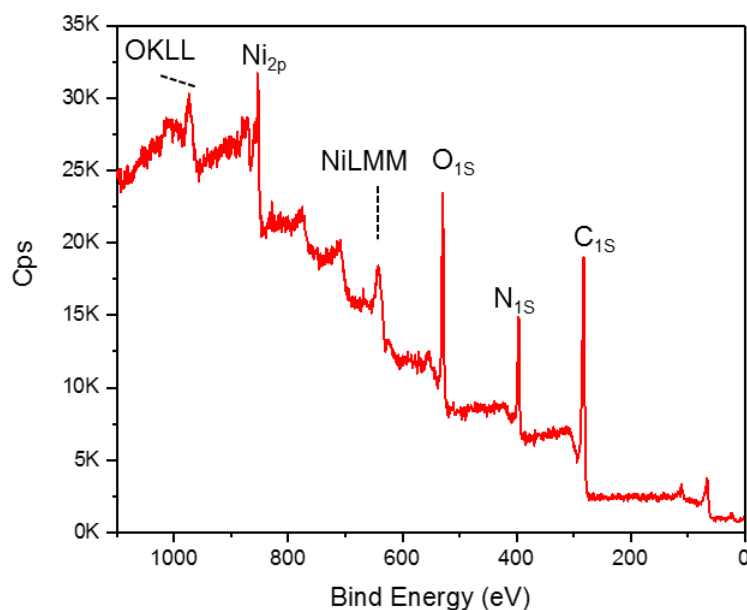

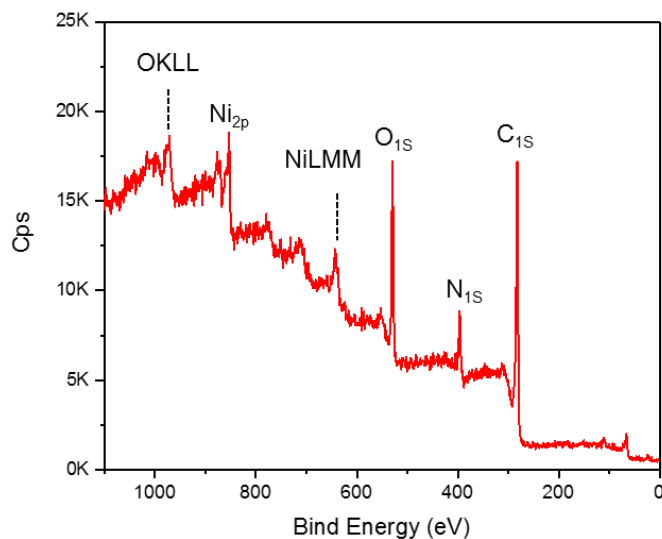

Figure S14. XPS survey spectrum of **NiNPc-Ni** showing C, N, O, Ni and Cu elements.

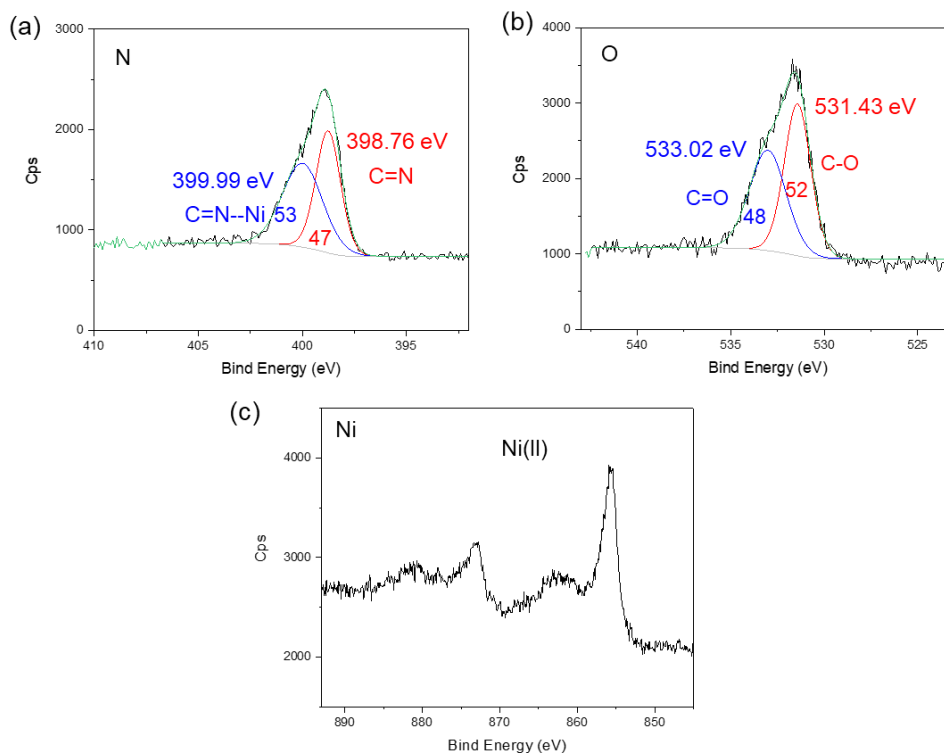

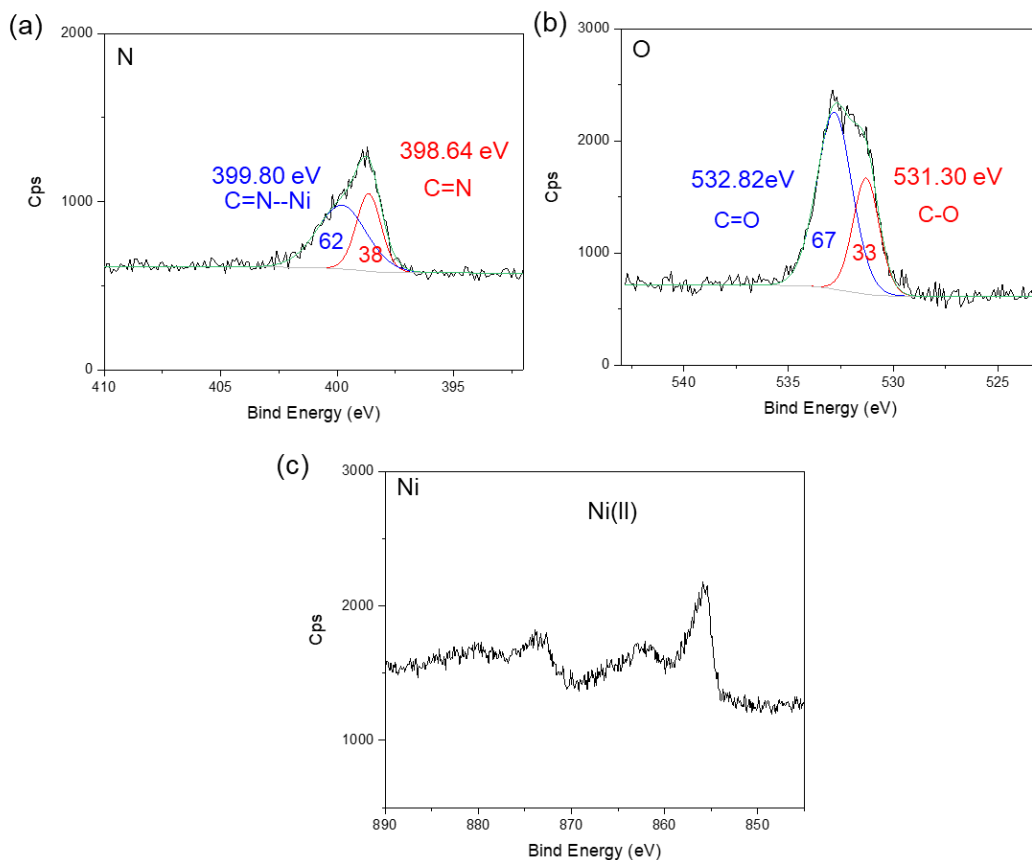

Figure S15. Deconvoluted XPS spectra of the **NiNPc-Ni**: (a) C1s, (b) N1s and (c) Ni2p. The black, grey, and green curve represent original data, background and the sum of the deconvoluted peaks, respectively. In (a) the blue curve corresponds to N(1s) in C=N-Ni and the red curve corresponds to C1s C=N-C. In (b) the red curve corresponds C-O and the blue curve corresponds to C=O.
Figure S16. XPS survey spectrum of **NiNPc-Cu** showing C, N, O, Ni and Cu elements.

**Figure S17.** Deconvoluted XPS spectra of the **NiNPc-Cu**: (a) C1s, (b) N1s, (c) Ni2p, and (d) Cu2p. The black, grey, and green curve represent original data, background and the sum of the deconvoluted peaks, respectively. In (a) the blue curve corresponds to N(1s) in C=N···Ni and the red curve corresponds to C1s C=N-C. In (b) the red curve corresponds C-O and the blue curve corresponds to C=O.
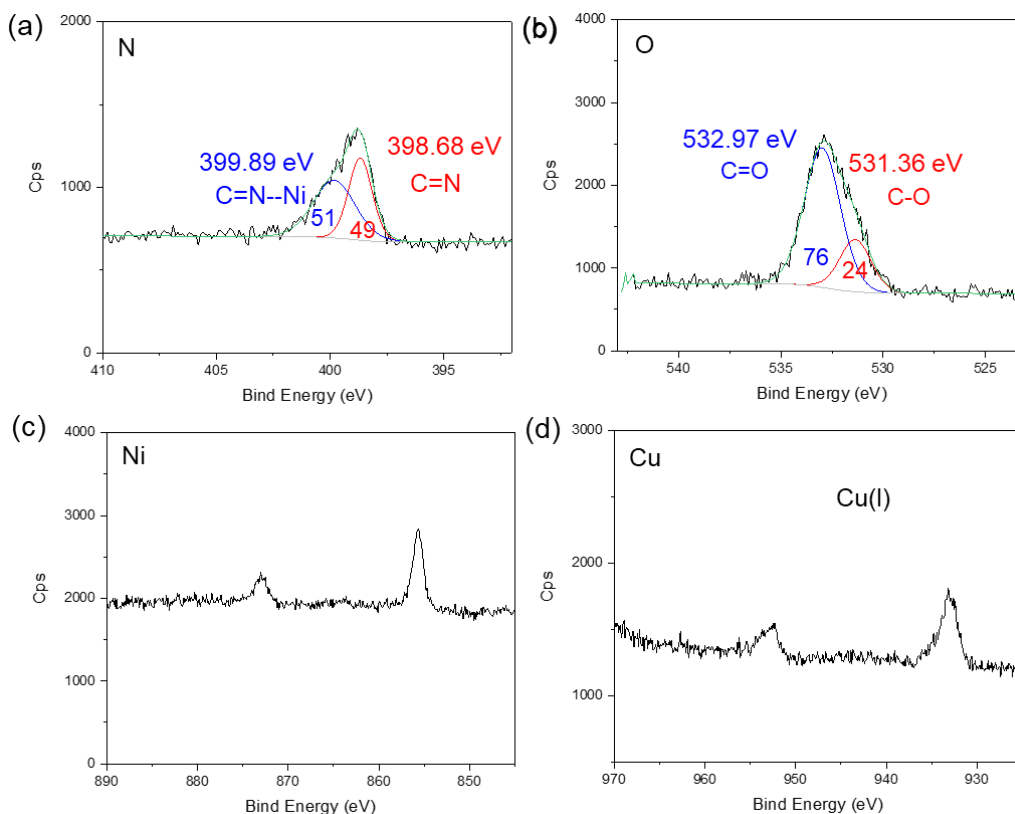

The XPS spectra revealed the presence of C, O, and N, along with Ni and/or Cu elements in **NiPc-M** and **NiNPc-M** MOFs (**Figure S10, S12, S14,** and **S16**), which coincide with the desired elemental composition of these MOFs.

Oxidation state analysis of metal and ligand in NiPc-Ni. High-resolution scans of the Ni2p showed two peaks with binding energies of ~855.6 and ~873.2 eV (2p3/2 and 2p1/2 levels, respectively) with the presences characteristic satellite peaks (**Figure S11**), indicating the oxidation state of the Ni is +2. These results are consistent with the experimental data reported by Sheberla et al.,[S4] and Dong et al.,[S5] where Ni in both Ni_3HITP_2 (HITP = 2,3,6,7,10,11-hexaiminotriphenylene) and Ni_3HTTP_2 (HTTP = 2,3,6,7,10,11-hexathioltriphenylene) showed +2 oxidation state. EPR spectrum of **NiPc-Ni** showed no visible peaks, which further supports the +2 oxidation state for Ni (**Figure S28**).

High-resolution scans of the O 1s region revealed two chemical environments with the peak with binding energies at 531.4 and 533.2 eV (**Figure S11**), which can be ascribed to two different O environment, C=O and C-O, respectively.[S6-7] The ratio of 48:52 further demonstrated that the ligand is likely in a (sq, sq, sq, sq) (sq=semiquinone) oxidation state, corresponding to a total charge of −4. Considering the theoretical ligand: metal ratio of 1:2, **NiPc-Ni** very likely has a charge neutral skeleton. High-resolution scans of the N 1s region further revealed two chemical environments with peaks found at 398.8 and 400.0 eV in a ratio of 47:53, which matches the presence of two different kinds of N atoms (Ni-coordinated and non-coordinated, in a 1:1 ratio) in the **NiPc** unit, suggesting the absence of large number of NH_4^+ acting as counter ions.

Oxidation state analysis of metal and ligand in NiPc-Cu. High-resolution scans of the Cu2p region produced two peaks with binding energies of ~933.1 and ~952.5 eV (2p3/2 and 2p1/2 levels, respectively) with very weak satellite peaks (**Figure S13**). The lack of obvious satellite structure suggests the absence of Cu(II).[S8] The Cu 2p 2/3 peak near 933.1 eV matches well with the binding energy value of a typical Cu 2p 2/3 peak of Cu(I) compound, which means the Cu(II) ion have been reduced by the **NiPc** ligand during the formation of **NiPc-Cu.** The XPS data is consistent with results analyzed from the EPR spectrum of **NiPc-Cu,** which showed only weak peak at g=2.02, probably due to the small amount of paramagnetic Cu^{2+} (**Figure S29**).

High-resolution scans of the O 1s region revealed two chemical environments with the binding energies at 531.4 and 533.2 eV (**Figure S13**), which can be ascribed to two different O environments: C=O and C-O, respectively.[S6-7] The ratio of 74:25 further demonstrated that the ligand is likely in a (sq, sq, q, q) (q=quinone) oxidation state, corresponding to a total charge of −2 charge on the ligand. The relatively higher oxidation states of the **NiPc,** compared with that in

NiPc-Ni, may be caused by the stronger oxidation ability of Cu^{2+}. High-resolution scans of the N 1s region revealed two chemical environments with peaks found at 399.0 and 400.0 eV in a ratio of 50:50, which matches the presences of two different kinds of N atoms (Ni coordinated and non-coordinated, in a 1:1 ratio) in the **NiPc** unit, thus eliminating the possibility of NH_4^+ acting as counter ions. Combining the theoretical ligand: metal ratio of 1:2 and the above analysis, it is suggested that **NiPc-Cu** has a charge neutral skeleton with a general formula of $(NiPc)_1Cu_2$.

Oxidation state analysis of metal and ligand in NiNPc-Ni. High-resolution scans of the Ni2p peak two peaks with binding energies of ~855.6 and ~873.2 eV (2p3/2 and 2p1/2 levels, respectively) with their characteristic satellite peaks (**Figure S15**), indicating the oxidation state of the Ni is +2.

High-resolution scans of the O 1s region revealed two chemical environments with binding energies at 531.3 and 532.8 eV (**Figure S15**), which can be ascribed to two different O environments, C=O and C-O, respectively. The ratio of 67:33 demonstrated that the ligand is likely in oxidation state with sq:q=2:1, corresponding to −8/3 state. The combination of the Ni and **NiNPc** in a 2:1 ratio doesn't afford a charge neutral framework, which suggests the presence of acetate oy hydroxide as the negative counter ions.

Oxidation state analysis of metal and ligand in NiNPc-Cu. High-resolution scans of the Cu2p region showed two peaks with binding energies of ~933.1 and ~952.8 eV (2p3/2 and 2p1/2 levels, respectively) with very weak satellite peaks (**Figure S17)**. The lack of obvious satellite structure suggests the absence of Cu(II).[S8] The Cu 2p 2/3 peak near 933.1 eV matches well with the binding energy value of a typical Cu 2p 2/3 peak of Cu(I) compound. Similar to the situation in **NiPc-Ni**, Cu(II) ions were likely reduced by the **NiNPc** ligand during the formation of **NiPc-Cu**. In addition, EPR showed very weak peak (*g*=2.03) likely originating d from the metal centered radical of Cu^{2+} (**Figure S31**), consistent with the scarcity of Cu^{2+} in **NiNPc-Cu.**

High-resolution scans of the O 1s region revealed two chemical environments with binding energies at 531.4 and 533.0 eV (**Figure S17**), which can be ascribed to two types of oxygen atoms, C=O and C-O, respectively.[S6-7] The ratio of 52:48 demonstrated that the ligand is likely in a (sq, sq, sq, sq) oxidation state, corresponding to an overall charge of −4. High-resolution scans of the N 1s region revealed two chemical environments with the peak positions found at 398.8 and 400.0 eV in a ratio of 53:47, which matched the presence of two different kinds of N atoms (Ni coordinated and non-coordinated, in a 1:1 ratio) in the **NiNPc** unit, eliminating the possibility of NH_4^+ acting as counter ions. Combining the theoretical ligand: metal ratio of 1:2 and the above analysis, **NiNPc-Cu** has a charge neutral skeleton with a general formula of $(NiNPc)_1Cu_2$, which is the same with

NiPc-Cu.

5. Elemental Analysis

Elemental analyses, including C, H, N were performed by Atlantic Microlab inc. using combustion method by automatic analyzers. The metal contents (Ni, Cu) were analyzed by ICP-MS. The results are listed below.

Table S1. Elemental analysis of **NiPc-Ni**.

Sample	Element	Theoretical[1]	Found
NiPc-Ni	C	47.54	36.30
	H	1.00	2.76
	N	13.96	15.20
	Ni	21.78	20.45

[1]Based on the formula (**NiPc**)$_1$Ni$_2$.

Table S2. Elemental analysis of **NiPc-Cu**.

Sample	Element	Theoretical[1]	Found

	H	1.58	3.73
	N	11.00	9.02
	Ni	5.76	4.88
	Cu	12.48	9.17

[1]Based on the formula (**NiNPc**)$_1$Cu$_2$.

6. Structure Analysis by Computational Study and Powder X-ray Diffraction

To build the crystal structure of **NiPc-Ni** and **NiPc-Cu**, model complexes composed of one phthalocyanine unit and four metal catecholate units were built. Their structures are shown in **Figure S18**. These model complexes were optimized by using B3LYP density-functional theory method with a basis set of 3-21G. The optimized structures of the model complexes were imported into Materials Studio. The initial crystal structures were constructed starting with a unit cell with the space group P1 with lattice parameters of $\alpha=\beta=\gamma=90$ °. The a and b values were estimated from the size of the model complexes. The c values were estimated according to the distance between the metal center of phthalocyanine unit and were chosen from the values calculated from the pXRD. The symmetries of the initial structures were then found and imposed to a higher symmetry of P4/mmm with a threshold of 0.01 Å pm (fine level). The crystal structure of **NiNPc-Ni** and **NiNPc-Cu** were also built using a similar approach.

NiNPc-Ni monomer

NiNPc-Cu monomer

Figure S18. Model complexes used for the construction of the initial MOF structures.

The geometry optimization, including energy minimization with cell parameters, were performed by using CASTEP module in Materials Studio with Perdew−Burke−Ernzerhof (PBE) generalized gradient approximation (GGA). The total energy change was set to less than 10^{-5} eV

and the magnitude of the largest force acting on the atoms was set to less than 0.03 eV A^{-1}. The cut-off energies were set at 500.0 eV. Calculation of the simulated powder diffraction patterns were performed by Materials Studio Reflex Plus Module. The optimized crystal structure the four MOFs with their lattice parameters are shown in **Figure S19**. Modeling of the staggered structures was performed in a similar manner but with the space group I4/mmm (**Figure S20**).

Figure S19. Views from *z* and *x* axes of modeled MOF crystal structures with eclipsed packing mode for (a) **NiPc-Ni**; (b) **NiPc-Cu**; (c) **NiNPc-Ni**; (d) **NiNPc-Cu**.
Figure S20. Views from *z* and *x* axes of modeled MOF crystal structures with staggered packing for (a) **NiPc-Ni**; (b) **NiPc-Cu**; (c) **NiNPc-Ni**; (d) **NiNPc-Cu**.

Powder X-ray diffraction (PXRD) data of **NiPc-Cu**, **NiPc-Ni**, **NiNPc-Cu** and **NiNPc-Ni** were collected using a Rigaku sixth generation MiniFlex X-ray diffractometer. Cu Kα radiation (λ = 1.5406 Å; 600 W, 40 kV, 15 mA) was focused using a planar Göbel mirror riding the Kα line.

7. Computational Study of the Electronic Properties

For computational study of electronic properties, including band structures, density of states, the functional GGA with PBE was employed with an energy cutoff set at 500 eV. The Brillouin zones were sampled using a $2 \times 2 \times 4$ k-point mesh in the Monkhorst‑Pack scheme.

Figure S26. Calculated electronic band structure (left) and density of state (right) for (a) **NiPc-Ni** and (b) **NiPc-Cu**, respectively. (c) Corresponding first Brillouin zone and high-symmetry K-points.

Figure S27. Calculated electronic band structure (left) and density of states (right) for (a) **NiNPc-Ni** and (b) **NiNPc-Cu**, respectively. (c) Corresponding first Brillouin zone and high-symmetry K-points.

DFT electronic band structure calculations suggested that bulk **NiPc-M** and **NiNPc-M** should be metallic. Both of **NiPc-M** and **NiNPc-M** MOFs exhibited dispersed electronic band structures that cross the Fermi level. The Dirac bands cross the Fermi level in both A−M and Γ−Z directions and have wide band dispersions of approximate 0.8-1.0 eV (**Figure S26a-b** and **Figure S27a-b**). Density of states analysis showed that considerable contributions were from the metal linkers, C, and O orbitals near the Fermi level, indicating the high degree of in-plane and out-of-plane π conjugation for these materials.

The high symmetry points in the first Brillouin zone are shown in **Figure S26c** and **Figure S27c**. In **NiPc-M** and **NiNPc-M,** bands cross the Fermi level in the out-of-plane direction, including A−M, Γ−Z, R−X directions, which indicates the metallic nature of materials. Because no bands cross the Fermi level through the in-plane directions (Z−R and X−Γ), the bulk materials are expected to be metallic in the *c* directions and semiconducting in the *ab* direction, suggesting that a dominant mechanism for conductivity in these **MPc** based MOFs maybe through conductive pathways along the *c*-axis.[S9] This electronic property is different from the M_3HIB_2 (M=Ni, Cu, HIB = hexaiminobenzene)[S10] and nickel bis(dithiolene) based MOFs[S11] where the in-plane charge transport is predicated to be more favorable than out-of-plane charge transport, and is similar with that of cobalt triphenylenehexathiolate framework where the out-of-plane transport is believed to be the dominant conductive pathway.[S9] As demonstrated above, **NiPc-M** and **NiNPc-M** MOFs adopt eclipsed stacking modes, which endows the stacking structures and alignment of the π-conjugated **NiPc** and **NiNPc** units, facilitating **NiPc**-on-**NiPc** (or **NiNPc**-on-**NiNPc**) and metal-on-metal pathways within 2D stacks. The out-of-plane charge-transport property is consistent with those found in the phthalocyanine-[S12-13] and porphyrin-based COFs,[S14-15] which usually exhibited high carrier mobility along the direction of the stacking due to the formation of periodic π-columns.

8. Electron Paramagnetic Resonance (EPR) Spectroscopy

EPR spectra were collected on a Bruker BioSpin Gmbh spectrometer equipped with a standard mode cavity. For each sample, about 2 mg material was used. The samples were flushed with N_2 for 15 minutes and then sealed in the EPR tube under N_2 atmosphere. The EPR spectrum was collected under liquid nitrogen temperature (77 K) with the parameters listed in the **Table S5**. **NiPc** and **NiNPc** ligand showed very intense peaks at *g* = 1.991 and 1.989, respectively, which are probably due to the adsorption of oxygen molecules (**Figure S28-S31**) or the existence of the partially oxidized species. **NiPc-Ni** showed **EPR** signal at *g*=1.988 from the ligand centered radical (**Figure S28**). **NiPc-Cu** showed relatively weaker metal centered EPR signal (*g*=2.021) compared with the ligand **NiPc (Figure S29)**. **NiNPc-Ni** showed peak at *g*=1.996 which originated from the

radial centered on the **NiNPc** ligand (**Figure S30**). In the EPR spectrum of **NiNPc-Cu**, peaks from the both the metal-centered (g=2.030) and ligand-centered radical (g=1.986) were shown (**Figure 31**).

Table S5. Parameters of EPR for ligands and MOFs.

Sample	sweep width/G	center field/G	modulation amplitude/G	microwave frequency/GHz	microwave power/mW
NiPc	2000	3400	4	9.673	0.0002026
NiNPc	2000	3400	4	9.658	0.0002026
NiPc-Ni	3000	3400	4	9.692	0.0002026

9. SEM and TEM

Scanning electron microscopy of the MOFs **NiPc-Ni, NiPc-Cu, NiNPc-Ni,** and **NiNPc-Cu** were obtained using a Hitachi TM3000 SEM. The material was pressed onto carbon conductive tape that was attached to the aluminum plate. The images were taken at a 10 mm working distance using a 15 kV beamline in a to 10^{-6} torr vacuum chamber.

Transmission electron microscopy was carried out in a Tecnai F20ST FEG TEM instrument. The sample was prepared by drop casting an acetone suspension (0.5 mg in 5 mL) of the MOFs onto a copper grid (300 mesh, 3.0 mm O.D). An operating voltage of 120 kV was used for imaging.

Energy dispersive X-Ray spectroscopy was collected using SDD X-ray microanalysis system with Octane Pro 10 sq. mm detector and TEAM software.

10.   Brunauer–Emmett–Teller (BET) Analysis

In order to assess the porosity of the MOFs, gas adsorption measurements were performed on an ASAP Plus 2020 (Mircromeritics, Norcross, Georgia) 3FLEX instrument with N_2 at 77K. To remove the residual high boiling point solvent used in the synthesis of the MOFs, the samples of MOFs were activated by soaking in acetone for 3 days during which the acetone was changed every 24 hours. The samples were then dried in the oven under vacuum (20 mTorr, 65 °C for 24 hours). Before gas adsorption measurements, the samples were degassed under vacuum at 80 °C for 12 hours. For BET calculations, a full isotherm with a fitting range of 0 to 0.3 P/P_0 was used. The Brunauer-Emmett-Teller (BET) surface areas for the four MOFs are listed below.

Table S6. BET surface areas of the MOFs.

	NiPc-Ni	NiPc-Cu	NiNPc-Ni	NiNPc-Cu
BET (m^2/g)	101	284	174	267
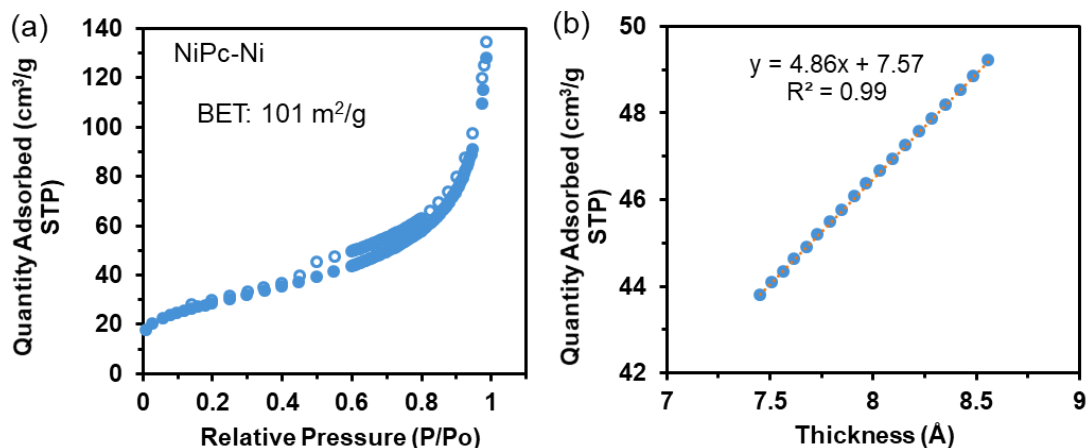

Figure S44. (a) Nitrogen sorption curves (filled circles: adsorption, open circles: desorption, STP=standard temperature pressure) and (b) *t*-Plot for nitrogen adsorbed at 77 K by activated **NiPc-Ni**. The BET surface area by the gas adsorption analysis is 101 m^2/g. The external surface area is 81 m^2/g and the micropore area is 20 m^2/g.

Figure S51. TGA curve of **NiNPc-Cu**.

12. Measurements of Conductivity

To make a pressed pellet, 50 mg of the MOF sample was put into a 6 mm inner-diameter split sleeve pressing die and pressed for 5 min under a pressure of approximately 1000 psi. A Signatone tungsten carbide four-point linear probe was employed to collect bulk conductivity measurements of the MOFs with a space between tips of 1.25 mm. We calculated the bulk conductivity measurements (S/cm) using **Equation S1**. Herein, I (A) is current, V is the voltage of cross the probes, s (cm) is distance of between the probes (1.25 mm), F (unitless) is the correction factor accounting for the diameter and thickness of the pellet.[S16-17]

$$\sigma = \frac{I}{V}\frac{1}{2\pi sF} \qquad \textbf{(S1)}$$
Figure S52. Representation of configuration for the measurement of conductivity by four-point probe method.

Table S7. Conductivity of the MOF measured by four-point probe method.

MOF	NiPc-Ni	NiPc-Cu	NiNPc-Ni	NiNPc-Cu
σ (S/cm)	7.22×10^{-4}	1.43×10^{-2}	1.78×10^{-2}	3.13×10^{-2}

13. Gas Sensing Experiments

13.1. Fabrication of Gas Sensors

1-4 mg of MOF samples was dispersed in 1 mL of deionized water. The mixture was then sonicated for 30 minutes and a homogeneous suspension was obtained. 10 µL of the suspension was drop casted onto interdigitated gold electrodes with 5 μm gaps (part NO. G-IDEAU5, purchased form Metrohm) (**Figure S53**), which was then allowed to dry in the air under room temperature in a dark area for about 18 hours before use.
Figure S53. Photograph of chemiresistive devices made by drop casting the suspension of MOFs in water onto 5 µm interdigitate gold electrodes.
Figure S54. Interferometry profile of the devices made from (a) **NiPc-Ni**, (b) **NiPc-Cu**, (c) **NiNPc-Ni**, and (d) **NiNPc-Cu** as shown in **Figure S53**. Arrows indicates the MOF films.

Table S8. The concentration of the MOF suspension and the resistances and film thickness of the device

Device	Suspension of MOF in H_2O	Film thickness (μm)	Resistance of devices (KΩ)[a]
NiPc-Ni	4 mg in 1mL	2-3	138 ± 15
NiPc-Cu	1 mg in 1 mL	0.7-1	0.73 ± 0.11
NiNPc-Ni	2 mg in 1 mL	0.5-1	7.90 ± 0.74
NiNPc-Cu	2 mg in 1 mL	0.5-1	8.72 ± 0.48

[a] Resistance was measured under ambient conditions under air using a two-point probe.
Figure S55. PXRD spectra of the MOFs before and after sonication in H_2O for 2 hours, showing that the MOFs maintained their crystallinities in suspension.

13.2. Sensing Experiments

The sensing performance of the fabricated devices was monitored in a sealed gas-sensing chamber at room temperature. An electrical feed-through and gas inlet and outlet were installed in the chamber. Dry N_2 was used as the balance/purging gas. A Sierra Micro-Trak and a Smart-Trak mass flow controllers were used in combination to deliver controlled concentrations of gases from custom-ordered pre-mixed tanks (10,000 ppm of NH_3 in N_2, and 100 ppm and 10,000 ppm of H_2S or NO in N_2) equipped with two-stage stainless steel regulators. Gas streams from the tanks were diluted with dry N_2 for delivery of controlled concentrations of gases. The concentrations of target gases (NH_3, NO, and H_2S) were adjusted by controlling the flow rates of the target gas and balance gas, which was achieved using two mass-flow controllers. The system was limited to mixing of one gas at a time with a dry N_2 or humidified N_2 stream. The flow of balance/purging gas was controlled at 0.5 or 1 L/min and the flow of the analyte was controlled at 0.3 to 4 mL/min. Before target gas exposure, the gas sensors were stabilized under N_2 exposure for at least 1 h to obtain a flat base line. For the sensing test of NH_3, NO, and H_2S, the exposure of target gas and purging gas was 30 minutes. Unless otherwise specified, all sensing experiments were performed under a constant applied voltage of 0.1 V.

The generation of 5000 ppm humidity stream was followed by the procedure previously reported by our group.[S18] Typically, the gas generator permeation tube was heated to 90 °C using the embedded oven with temperature control, and loaded with a vial of deionized water. Total span

gas flow through the oven was set to 417 mL/min. (During a calibration time of 1169.3 min, 1.9569 g of H$_2$O in the vial was lost. The concentration of the stream can be calculated as $c = \frac{1.9569\text{ g}}{18.01\text{ g mol}^{-1}} \times 22.41\ L\ mol^{-1} \times \frac{1}{0.417\ L/min \times 1169.3\ min} = 5 \times 10^{-3}$ v/v=5000 ppm.) The resulting vapor stream was mixed with the gas stream delivered by the mass flow system using a Y-connection. The dilution stream of nitrogen usually employed for the dilution of tank gases was not used, with the humid nitrogen from the gas generator serving as the dilution vapor. The dilution vapor (5000 ppm water) was mixed with the controlled stream from the mass flow controllers (1.7 mL/min) to deliver a humidified stream of a single gaseous analyte at 40 ppm.

Raw current data (collected under constant applied voltage) was normalized and converted to normalized conductance according to **Equation S2**, wherein I_o = initial current and I = current at various points during measurement.

$$-\frac{\Delta G}{G_0} = -\frac{I - I_0}{I_0} \times 100\% \qquad \textbf{(S2)}$$

The theoretical limits of detection (LOD) were calculated using reported protocols.[S19-20] First, the root mean squared (rms) value — representing the noise-based deviation in $-\Delta G/G_o$ — was calculated using the baseline trace before exposure to analyte. We took 600-1000 consecutive points (*N*) and fit the data to a polynomial (5th order). We then calculated sum of squared residuals (SSR) from **Equation S3**, where y_i is measured $-\Delta G/G_o$ and y is the value calculated from the polynomial fit. The root-mean-square deviation (*RMS*) was then calculated by **Equation S4**. We plotted concentration of analyte versus response ($-\Delta G/G_o$) after a specific exposure time and isolated the range of values wherein this relationship was linear (**Figure S57, S59, S66b, S68b, S74, and S76**). Linear regression provided an equation of best-fit (slope = *m*). With these values, we extrapolated the theoretical LOD from **Equation (S5)**.

$$SSR = \sum(y_i - y)^2 \qquad \textbf{(S3)}$$

$$RMS = \sqrt{\frac{SSR}{N}} \qquad \textbf{(S4)}$$

$$LOD = 3 \times \frac{RMS}{m} \qquad \textbf{(S5)}$$

Device to device reproducibility is quantified by coefficient of variation (relative standard deviation), and the data is summarized in **Table S18**.

The degree of saturation (DS) of the sensor, which is defined as the ratio of the quantity of the analyte adsorbed after a specific amount of time by the sensor to the quantity of the analyte

absorbed upon the saturation,[S21] was calculated using the **equation S6**. This calculation was based on the assumptions that saturation point achieved after 30 minutes exposure and that the current change (ΔI_t) of the device after t min exposure is linear proportional to the quantity of the adsorbed analytes (C_t) by the sensing materials.[S22]

$$DS\% = \frac{C_t}{C_O} = \frac{I_{1.5} - I_0}{I_{30} - I_0} \times 100\% \qquad \textbf{(S6)}$$

In this equation, I_0, $I_{1.5}$, and I_{30} are the current of the devices after analyte dosing for 0, 1.5, and 30 min exposure, respectively, and C_o is the quantity of the adsorbed analytes upon saturation.

13.2.1. NH₃ Sensing
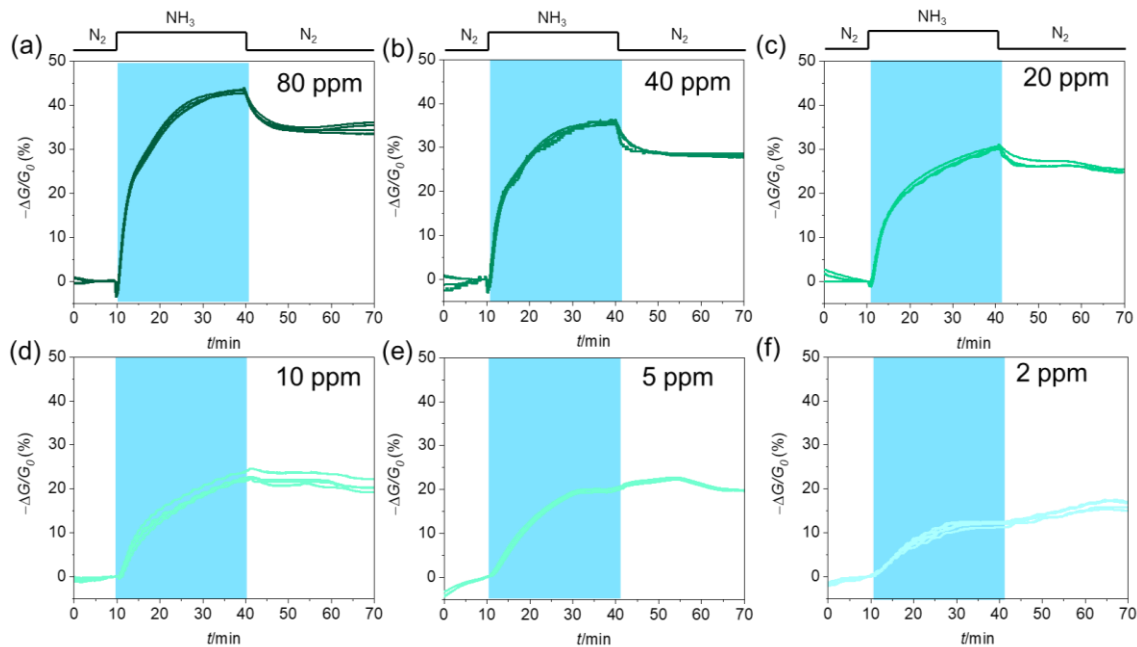

Figure S56. Responses of **NiPc-Ni** devices to (a) 80, (b) 40, (c) 20, (d) 10, (e) 5, and (f) 2 ppm of NH₃. For each concentration, 3–4 freshly prepared devices were used at an applied voltage of 1.0 V.

Figure S57. Response of **NiPc-Ni** device as a function of NH_3 concentration. The values of response after the exposure for 1.5, 5, 10, 20 and 30 min were plotted. The slopes of the curves are 0.17, 0.27, 0.33, 0.56, and 0.97. SSR is 0.3061. $N=1000$, RMS is 0.017495.

NiNPc-Cu	1.28	1.27	0.12	0.25	9.79	4.14

13.2.4. Analysis for Initial Rates of Response

Analyzing the initial rate of response of the sensor is a convenient technique that can enable concentration-dependent measurement on a short timescale (less than a minute). The application of initial rate analysis is well-established in biochemical sensors.[S23-24] The initial rate analysis usually takes a significantly shorter time to complete a measurement compared with the steady-state analysis.[S23] At the initial stage of the analyte exposure, only a very small portion of the activate sites on the surface of the materials is occupied. Considering that the sensor usually works in an environment it is exposed to low concentrations of analytes, it is rational to assume that, at the initial stage of the analyte exposure, the concentration of the analytes will be much smaller than the density of unoccupied active sites on the sensing material. Consequently, the reaction/interaction/binding event between the analyte and active sites on the surface of the sensing material can be treated as a pseudo-first-order reaction.[S25] In this case, the initial rate of the analyte binding will be proportional to the concentration of the analyte. Since the response of the sensor can be proportional to the quantity of analytes bound to the surface of the sensing material based on the site-binding mechanism for chemiresistive sensing,[S26] The initial rate of response can thus be expected to be proportional to the concentration of the analyte.
Figure S81. (a) Responses of **NiPc-Ni** devices to 80, 40, 20, 10, 5, and 2 ppm of NH_3 after 1 min's exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
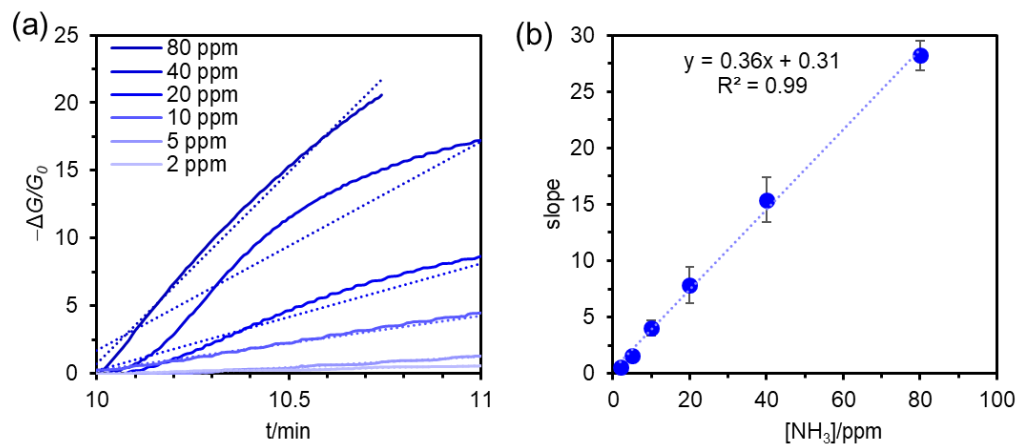

Figure S82. (a) Responses of **NiPc-Cu** devices to 80, 40, 20, 10, 5, and 2 ppm of NH_3 after 1 min's exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
Figure S83. (a) Responses of **NiPc-Ni** devices to 80, 40, 20, 10, 5, 2, 1, 0.5, and 0.2 ppm of H_2S after 1 min exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
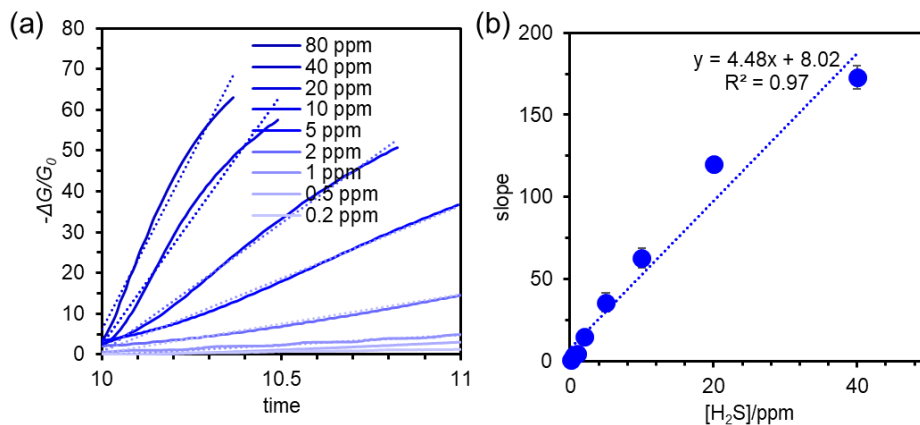

Figure S84. (a) Responses of **NiPc-Cu** devices to 80, 40, 20, 10, 5, 2, 1, 0.5, and 0.2 ppm of H_2S after 1 min exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
Figure S85. (a) Responses of **NiPc-Ni** devices to 1, 0.5, 0.2, 0.08, 0.04, and 0.02 ppm of NO after 1 min exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
Figure S86. (a) Responses of **NiPc-Cu** devices to 1, 0.5, 0.2, 0.08, 0.04, and 0.02 ppm of NO after 1 min's exposure and the linear fitting of the response. (b) The slope of the fitting as a function of concentration.
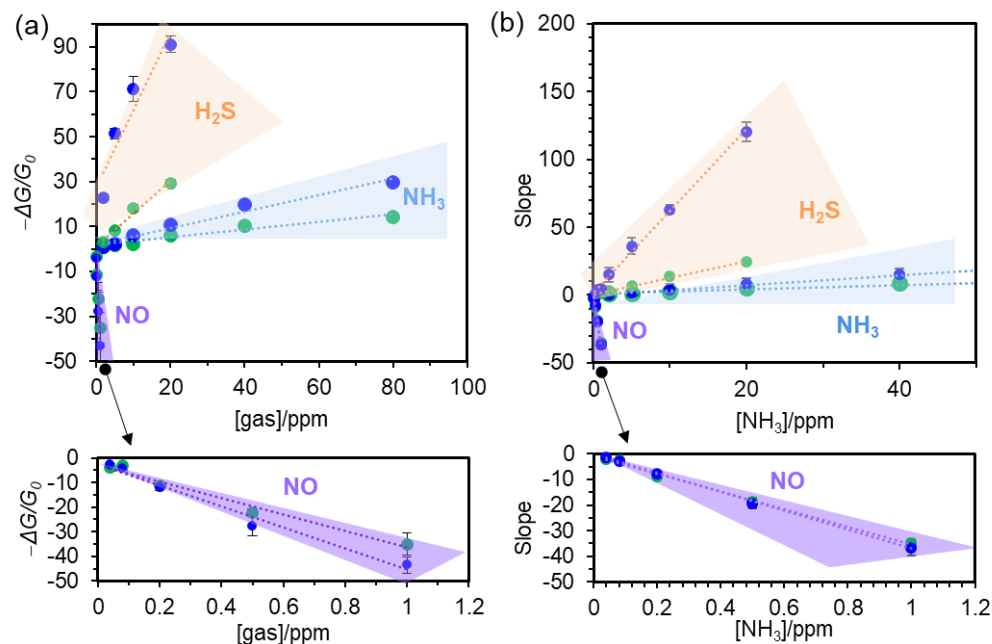

Figure S87. (a) Relationship between the response ($-\Delta G/G_0$) after 1.5 min exposure of gases and gas concentrations. (b) Relationship between the slope of the response (($-\Delta G/G_0$)/Δt) during the first 1 min exposure to gases and gas concentrations. Both the response ($-\Delta G/G_0$) and slope of the response (($-\Delta G/G_0$)/Δt) analysis allows the quick discrimination of the three gaseous analytes and their concentrations within a short time of 1.5 min and 1.0 min, respectively. The insets show the fitting range for NO.

Table S19. Parameters for principal component analysis for 40 ppm NH_3, 40 ppm H_2S, and 1.0 ppm NO.

MOFs	Gas	X1 (response at 30 min)	X2 (slope of response at 1 minutes)	X3 ($I_0/I_{30\ min}$)	X4 (response at 20 min)	X5 (response time)	X6 (recovery ratio)	X7 (response value after recovery)
NiPc-Ni	NH_3	35.71	9.47	1.56	34.3	15.4	20.18	28.5
	H_2S	61.62	43.17	2.61	61.1	4.1	2.62	60
	NO	-657.54	-34.37	0.13	-470	27	31.56	-450
NiPc-Cu	NH_3	30.08	15.42	1.43	28.7	9.3	80.05	6
	H_2S	99.56	170.01	227.27	99.2	1.07	0.56	99
	NO	-397.28	-36.69	0.20	-345	21.8	1.83	-390
NiNPc-Ni	NH_3	26.80	7.28	1.37	23.3	21	10.45	24
	H_2S	48.12	5.43	1.93	43	20.2	0.25	48
	NO	-389.75	-45.40	0.20	-360	10	25.59	-290
NiNPc-Cu	NH_3	50.23	48.00	2.01	48.2	11.6	42.27	29
	H_2S	95.20	103.00	20.82	94.6	4.7	1.26	94
	NO	-41.67	-10.70	0.71	-45	5	56.80	-18

Response time is the amount of time it takes to get to 90% of response values at 30 min exposure.

Recovery ratio is defined as $\frac{I_{30\ min} - I_{after\ recovery}}{I_{30\ min} - I_0} \times 100\%$.

The PCA was performed by using Statistics selection of OriginLab.

Table S20. Representative examples of NH_3, H_2S, and NO detection by NiPc-M MOFs and other nanomaterials/methods.

material	analyte	Sensing devices or method	LOD	Detection range	reference
NiPc-Ni	NH_3	chemiresistor	0.05-0.31 ppm	2-80 ppm	This work

13.3. XPS and EPR Studies of Gas Exposure

For each sample used for XPS and EPR test, about 2 mg and 6 mg of MOF materials were used for analytes exposure, respectively. The analyte-exposed samples were prepared by a gas purging cycle of N_2 (1 L/min, 30 minutes)—analyte (a controlled concentration, 30 min)—N_2 (1 L/min, 30 minutes) on pristine MOF materials. The concentrations of the analytes are controlled at 40 ppm for H_2S and NH_3, and 1 ppm for NO, respectively. The analyte-exposed samples were immediately used for EPR tests using the operation conditions as described in **Section 8**. For the XPS tests, the analyte exposed samples were prepared about 18 hours in advance, and were stored under N_2 at room temperature until the testing was done. The XPS analysis was performed under a pressure of ~10^{-9} psi.
Figure S88. Comparison of the O1S XPS spectrum of (a) pristine **NiPc-Ni**, (b) **NiPc-Ni** with the exposure of H_2S (40 ppm for 30 minutes), and (c) **NiPc-Ni** with the exposure of NO (1 ppm for 30 minutes). Deconvoluted peaks of O1S from C=O and C-O are in blue and red, respectively, and the ratios (%) of peak area are given accordingly. The origin curves are the sum of the deconvoluted peaks.
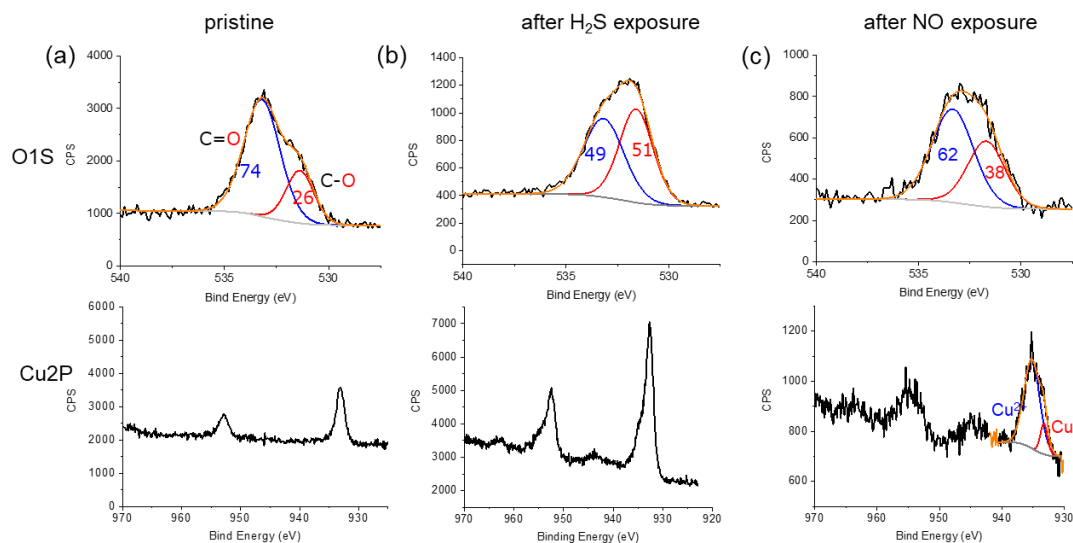

Figure S89. Comparison of the O1S and Cu2P XPS spectrum of (a) pristine **NiPc-Cu**, (b) **NiPc-Cu** after exposure to H_2S (40 ppm for 30 minutes), and (c) **NiPc-Cu** after the exposure to NO (1 ppm for 30 minutes). Deconvoluted peaks of O1S from C=O and C-O are in blue and red, respectively, and the ratios (%) of peak area are given accordingly. The deconvoluted Cu2p peaks in (c) in blue and red are Cu^{2+} and Cu^+, respectively. The origin curves are the sum of the deconvoluted peaks.
Figure S90. Comparison of the EPR spectrum of (a) **NiPc-Ni** and (b) **NiPc-Cu** with (solid line) and without (dash line) the exposure of 40 ppm H_2S for 30 minutes.
Figure S91. Comparison of the EPR spectrum of (a) **NiPc-Ni** and (b) **NiPc-Cu** with (solid line) and without (dash line) the exposure of 1 ppm NO for 30 minutes.
