## BoltzTraP method

The electrical transport properties were calculated using BoltzTrap code based on a semi-classic Boltzmann transport theory [1].

Under the approximation, the electrical conductivity and electric thermal conductivity as function of temperature T and chemical potential  $\mu$  can be calculated from the following equations:

$$\sigma_{ij}(T, \mu) = \frac{1}{\Omega} \int g_{ij}(\xi) \left[ -\frac{\partial f_\mu(T, \xi)}{\partial \xi} \right] d\xi \quad (1)$$

Here e,  $\Omega$  and  $\xi$  represent the electron charge, reciprocal space volume, and band energy, respectively.  $\frac{\partial f_\mu(T, \xi)}{\partial \xi}$  is the differential of Fermi function.  $g_{ij}(\xi)$  denotes transport distribution function, shown as

$$g_{ij}(\xi) = \frac{e^2}{N} \sum_{n, \vec{k}} \tau_{n, \vec{k}} v_i(n, \vec{k}) v_j(n, \vec{k}) \frac{\delta(\xi - \xi_{n, \vec{k}})}{d\xi} \quad (2)$$

where N is the k-points number in the entire BZ.  $\xi_{n, \vec{k}}$  are the energy for n-th band at wave vector  $\vec{k}$ ,  $v_i(n, \vec{k})$  is the corresponding velocity as defined as

$$v_i(n, \vec{k}) = \left( \frac{1}{h} \right) \frac{\partial \xi}{\partial \vec{k}} \quad \text{The relaxation time is treated as independence with n and}$$

$\vec{k}$  namely as a constant ( $\tau_{n, \vec{k}} = \tau$ ). The electrical transport parameters were calculated

based on the eigenvalues from PBE functional. To accurately predict the transport parameters, much denser k-mesh ( $20 \times 20 \times 1$ ) was used for the integrations in 1<sup>st</sup> BZ.
