Section 1: Details of Nudged Elastic Band (NEB) Method and Molecular Dynamics (MD) Simulations

1.1 Simulation Systems Setup

The GTP-analog, GppNHp-bound K-Ras^{Q61H} (PDB ID: 3GFT) and GDP-bound K-Ras (PDB ID: 4LPK)[1] were extracted from the Protein Data Bank (PDB) as the two end-point structures, the former active form as the starting structure and the latter inactive form as the ending structure. In 3GFT, residue H61 was mutated back to Q61 to represent the wild type K-Ras and the GppNHp was modified to GDP to mimic the effect of the hydrolysis of the γ-phosphate. In addition to two end points, 20 replicas linking the start and the end points were generated using nudged elastic band (NEB) method (please see the following section). Thus, 22 systems were used as the initial structures for explicit solvent molecular dynamic (MD) simulations.

1.2 Nudged Elastic Band (NEB) Method

To dissect the Ras deactivation process, NEB method[2-3], a powerful tool to probe the transition pathway of protein dynamics was carried out. In NEB, a series of replicas, referred to as "images" of the system under study, are created and connected to each other with strings and they form a discrete representation of the path from the start, GTP-bound active state, to the end, GDP-bound inactive state. Energy minimization of the overall system, but with the start and the end structures fixed, generates a minimum energy path (MEP). Each replica between the start and the end is connected to the previous and the next by "springs" along the MEP, which can maintain the replicas from sliding down the energy landscape onto the adjacent replicas. In NEB, as shown in Eq. (1), the total force F on each replica, i, is decoupled into a parallel force, $F_i^{\parallel}$, and a perpendicular force, $F_i^{\perp}$, by the tangent vector. $F_i^{\parallel}$ accounts for the artificial springs connecting each replica (Eq. (2)), where k_i equals to the spring constant between replica P_i and P_{i+1}, and P is the 3N dimensional position vector of replica i, and τ is the 3N dimensional tangent unit vector describing the path. $F_i^{\perp}$ is calculated by subtracting out the parallel component from F, as shown in Eq. (3), where $\nabla V(P_i)$ is the energy gradient with respect to the atomic coordinates in the whole system in replica i.

$$F_i = F_i^{\parallel} + F_i^{\perp} \tag{1}$$

$$F_i^{\parallel} = [(k_{i+1}(P_{i+1} - P_i)) - k_i(P_i - P_{i-1})) \cdot \tau]\tau \tag{2}$$

$$F_i^{\perp} = -\nabla V(P_i) + ((\nabla V(P_i)) \cdot \tau)\tau \tag{3}$$

In NEB calculation, the K-Ras in the active form (PDB ID: 3GFT), with GppNHp modified into GDP, and K-Ras in the inactive form (PDB ID: 4LPK) were referred to as the start and end points. The modified AMBER FF03 force field in AMBER 14 was assigned to K-Ras and the general AMBER force field (GAFF) was used to treat the GDP[4,5]. K-Ras systems were first solvated using the TIP3P water model and counterions were added to maintain electroneutrality of the systems. Then, 20 replicas were created, which stretch along the Active→Inactive pathway and were connected to each other by strings. Neighbouring replicas were first fit to each other using RMSD (root means square deviation) with respect to the backbone atoms within the corresponding systems. Then, NEB force decoupling was applied to the backbone atoms in each replica. During the heating stage from 0 to 300K, the spring force was set to 10 kcal mol^{-1} Å^{-2} with a Langevin collision frequency of 1000 ps^{-1}, while in the following simulated annealing, equilibrium and slow cooling processes, a larger spring force of 50 kcal mol^{-1} Å^{-2} was used. The simulated annealing method was employed for the optimization of the pathway from active state to the inactive state and it was carried out based on previously reported workflow[6,7].

1.3 MD Simulations

MD simulations were carried out with AMBER 14. Modified AMBER ff03 force field[4,5] was applied to the K-Ras protein and GDP was treated with the general AMBER force field (GAFF) and its related parameters were obtained from the AMBER parameter database (www.pharmacy.manchester.ac.uk/bryce/amber). The overall systems were first solvated in truncated octahedral boxes with the TIP3P water molecules and were neutralized with counterions. Then, the complex systems were subject to two-round energy minimization. In the first step, the protein scaffolds were restrained and a 5000-step maximum minimization cycle was carried out and in the second step, the whole systems were minimized without any restrictions. Subsequently, the systems were heated from 0 K to 300 K within 300 ps, and equilibration at 300 K

for 700 ps followed, both of which were under a positional restraint of 10 kcal mol^{-1} Å^{-2} in a canonical ensemble (NVT). Finally, for 22 initial structures (the start and the end points and 20 replicas inserted by NEB method), each was performed 10 independent MD runs with random initial velocities. 200-ns MD simulations were carried out for each system, which resulted in 220 independent trajectories with a cumulation of 44-μs length. The particle mesh Ewald method[8] was employed for the incorporation of the long-range electrostatic interactions within the systems and a 10 Å cutoff was introduced for the short-range electrostatics and van der Waals interactions. All covalent bonds engaging hydrogen atoms were restricted using the SHAKE method.

Section 2: The Choice of Two Metrics to Project the Simulation Data to Obtain the Conformational Landscape of Ras Deactivation

Structural superimposition of the crystal structures of GppNHp- and GDP-bound Ras yields a root-mean square deviation (RMSD) of 1.91 Å for all of the backbone atoms. The overlapped structures show that the most significant conformational differences between the two structures are derived from the switch I and switch II domains (Figure 1C). If the switch I and switch II domains are excluded in the calculation, the backbone RMSD is 0.58 Å for all of the backbone atoms between the remaining elements of the two structures, further supporting the notion that the major conformational differences between GppNHp- and GDP-bound Ras are localized to the switch I and II domains. Notably, in the GppNHp-bound state, Tyr32 on the switch I domain is in the "up" conformation, denoted as "Tyr32$_{up}$", and the α2-helix on the switch II domain is positioned in the "inward" conformation, denoted as "α2-helix$_{in}$" (Figure 1D). In contrast, in the GDP-bound state, Tyr32 on the switch I domain is in the "down" conformation, denoted as "Tyr32$_{down}$", and the α2-helix on the switch II domain is positioned in the "outward" conformation, denoted as "α2-helix$_{out}$" (Figure 1D). Based on this observation, we chose the following two order parameter pairs to project the simulation data to obtain the conformational landscape. One is defined by the distance (d) from the hydroxyl oxygen of the switch I residue Tyr32 to the Cα atom of the P loop residue Gly12, which reflects the conformational changes of the switch I domain, and the other is defined by the dihedral (φ) calculated by the Cα atoms of Ile24 (α1-helix), Ala66 (α2-helix), Glu76 (α2-helix), and Val81 (β4), which monitors the conformational rotations of the α2-helix of the switch II domain. Furthermore, crystallography data were projected onto the reaction path sampled by MD simulations and their distributions are similar (Figure 2B), indicating the reasonable agreement between them. Therefore, it is feasible to choose the two order parameter pairs (d and φ) to project the simulation data to obtain the conformational landscape.

Section 3: Convergence Test of the Free Energy Landscape Using Different Simulations Datasets

To confirm that our MD simulations are sufficient to construct a reliable free energy landscape, we assessed the convergence of the free energy landscape by choosing different subsets from the complete simulation dataset. Six subsets of the complete dataset were extracted with different accumulated simulation times by truncated each MD simulation into varied length, namely 33 μs (220×150 ns) (Figure S1A), 35.2 μs (220×160 ns) (Figure S1B), 37.4 μs (220×170 ns) (Figure S1C), 39.6 μs (220×180 ns) (Figure S1D), 41.8 μs (220×190 ns) (Figure S1E), and 44 μs (220×200 ns) (Figure S1F). To check whether the sampling is converged or not, we projected the MD snapshots from each subset onto the same two order parameters. As shown in Figure S1, all datasets demonstrate similar free energy landscapes and no extra metastable state appears while increasing the simulation time, suggesting that the current timescale of MD simulations is enough to explore the major substates of the Ras deactivation pathway.
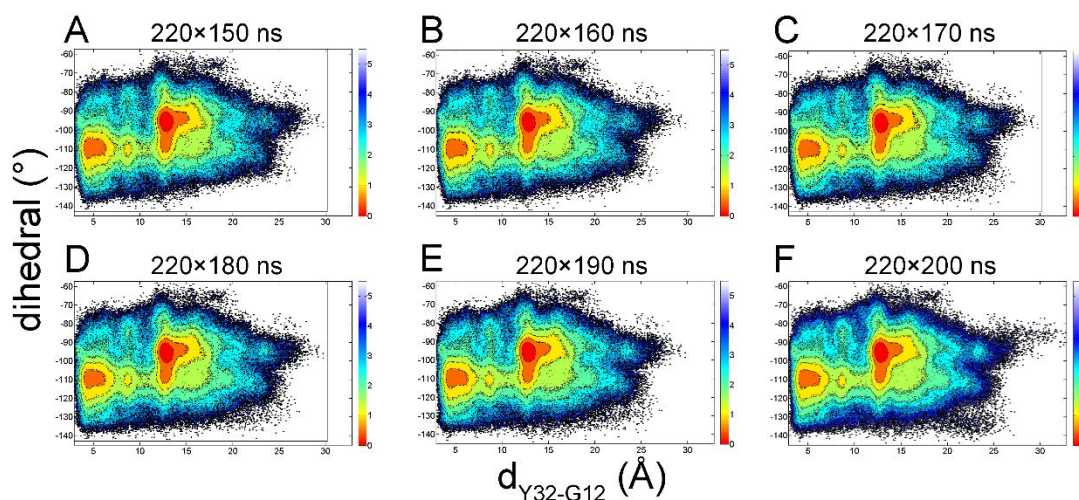

Figure S1. Projections of different subsets of the complete simulation dataset onto the two same order parameters (unit in *kcal/mol*), with the aggregated time of 33 μs (A), 35.2 μs (B), 37.4 μs (C), 39.6 μs (D), 41.8 μs (E), and 44 μs (F).

Section 4: Comparison of Intermediate State with the Active and Inactive states of Ras
Figure S2. Stepwise deactivation process of Ras. Representative structures captured by MD simulations of active (cyan), intermediate (green), and inactive (pink) states of Ras. Tyr32 is represented by stick models and it exhibits "up"→"between"→"down" transitions along the Ras deactivation path. The α2-helix stays still in the "α2-helix$_{in}$" conformation from the active to the intermediate states. It is positioned at the "α2-helix$_{out}$" conformation in the inactive form of Ras.

Section 5: Comparing Our Intermediate State Obtained from MD Simulations with the Proposed Intermediates Determined by Crystallography

Currently, crystal structures of two Ras mutants (A59G and Q61G) whose structures have proposed to resemble the intermediates in the conformational transition from Ras-GTP to Ras-GDP. The two mutations (A59G and Q61G) are located at the N-terminal switch II domain. The resulting mutations lead to the enhanced flexibility of the switch II domain, facilitating the conformational variation of switch II domain.

Figure S3. (A) Cartoon representation of the backbone superimposition of crystal structures of Ras^{WT}-GppNHp (PDB ID 6GOD, cyan), Ras^{WT}-GDP (PDB ID 4LPK, pink), Ras^{A59G}-GppNHp (PDB ID 1LF0, light blue), and Ras^{A59G}-GDP (PDB ID 1LF5, red). (B) Cartoon representation of the backbone superimposition of crystal structures of Ras^{WT}-GppNHp (PDB ID 6GOD, cyan), Ras^{WT}-GDP (PDB ID 4LPK, pink), Ras^{Q61G}-GppNHp (PDB ID 1ZW6, purple), and Ras^{Q61G}-GDP (PDB ID 1ZVQ, orange). Cartoon representation of the backbone superimposition of crystal structures of Ras^{A59G} and Ras^{Q61G} in the GppNHp- (C) and GDP-bound (D) states. The significant conformational differences of the switch I and II domains are colored correspondingly, the remaining elements showing less conformational changes colored by gray. Residue Tyr32, GppNHp, and GDP are depicted by stick models.

In the Ras^{A59G} mutant, crystal structures of Ras^{A59G} bound to GppNHp (Ras^{A59G}-GppNHp) (PDB ID 1LF0) and GDP (Ras^{A59G}-GDP) (PDB ID 1LF5) were determined, respectively. As shown in Figure S3A, backbone superimposition of crystal structures of Ras^{A59G}-GppNHp and Ras^{A59G}-GDP onto those of Ras^{WT}-GppNHp and Ras^{WT}-GDP shows that the switch I domain in the GppNHp- and GDP-bound Ras^{A59G} states adopts a conformation similar to that observed in the Ras^{WT} states, respectively; in contrast, the switch II domain in the Ras^{A59G} mutant shows different conformational variations compared to the Ras^{WT} state. In the GppNHp-bound state, the switch I domain in the Ras^{A59G}-GppNHp state adopts a conformation similar to that observed in the Ras^{WT}-GppNHp state. However, in the GDP-bound state, the α2-helix of the switch II domain exhibits a significant conformational change that is in the "between" conformation (denoted as "α2-helix$_{between}$"), which is positioned between the "α2-helix$_{in}$" in the active GTP-bound state and the "α2-helix$_{out}$" in the inactive GDP-bound state.

In the Ras^{Q61G} mutant, crystal structures of Ras^{Q61G} bound to GppNHp (Ras^{Q61G}-GppNHp) (PDB ID 1ZW6) and GDP (Ras^{Q61G}-GDP) (PDB ID 1ZVQ) were determined, respectively. Figure S3B shows backbone superimposition of crystal structures of Ras^{Q61G}-GppNHp and Ras^{Q61G}-GDP onto those of Ras^{WT}-GppNHp and Ras^{WT}-GDP. Similar to the Ras^{A59G} mutant, the switch I domain in the GppNHp- and GDP-bound

Ras^{Q61G} as well as the switch II domain in the GppNHp-bound Ras^{Q61G} adopt similar conformations observed in the Ras^{WT}-GppNHp and Ras^{WT}-GDP states. The α2-helix of the switch II domain in the Ras^{Q61G}-GDP is also in the "α2-helix$_{between}$" conformation.

Backbone superimposition of crystal structures of Ras^{A59G}-GppNHp and Ras^{Q61G}-GppNHp (Figure S3C) shows that the switch I domain of Ras^{A59G} and Ras^{Q61G} in the GppNHp-bound state is similar, while residues 61−64 of the N-terminal switch II region form an additional short 3_{10} helix that extends α2-helix by one turn in the Ras^{Q61G}-GppNHp compared to that in the Ras^{A59G}-GppNHp. Figure S3D shows backbone superimposition of crystal structures of Ras^{A59G}-GDP and Ras^{Q61G}-GDP. Both conformations of the switch I and II domains in the Ras^{A59G} and Ras^{Q61G} are identical in the GDP-bound state.

To further reveal the differences between our identified intermediate obtained from MD simulations and the proposed intermediates (A59G and Q61G) by crystallography, we superimposed the structures of our identified intermediate, Ras^{A59G}-GDP, and Ras^{Q61G}-GDP onto those of Ras^{WT}-GppNHp and Ras^{WT}-GDP states. As shown in Figure S4, the residue Tyr32 of the switch I domain in our identified intermediate is in the "between" conformation (Y32$_{between}$), which is different from that in the crystal structures of Ras^{A59G}-GDP and Ras^{Q61G}-GDP where it is in the "down" conformation (Y32$_{down}$) in both structures similar observed in the crystal structure of Ras^{WT}-GDP. However, the α2-helix of the switch II domain in our identified intermediate is still in the "inward" conformation (α2-helix$_{in}$) similar observed in the crystal structure of Ras^{WT}-GppNHp, which is different from that in the crystal structures of Ras^{A59G}-GDP and Ras^{Q61G}-GDP where it is in the "between" conformation (α2-helix$_{between}$) in both structures.

Based on above analyses, our identified intermediate is markedly different from crystal structures of Ras^{A59G} and Ras^{Q61G} along the reaction path of Ras hydrolysis. Our identified intermediate represents a conformational state where the switch I domain is in the "between" conformation along the reaction path, while the conformational transition of the switch II domain is not to start. However, both crystal structures of Ras^{A59G} and Ras^{Q61G} in the GDP-bound state represent a conformational state where the

conformational transition of the switch I domain is fully completed, while the transition of the switch II domain is in the "between" conformation along the reaction path. Therefore, our identified intermediate precedes the structures of Ras[A59G]-GDP and Ras[Q61G]-GDP along the reaction path of Ras hydrolysis.
Figure S4. Cartoon representation of the backbone superimposition of structures of Ras[WT]-GppNHp (PDB ID 6GOD, cyan), Ras[WT]-GDP (PDB ID 4LPK, pink), Ras[WT]-GDP (our identified intermediate, green), Ras[A59G]-GDP (PDB ID 1LF5, red), and Ras[Q61G]-GDP (PDB ID 1ZVQ, orange). The significant conformational differences of the switch I and II domains are colored correspondingly, the remaining elements showing less conformational changes colored by gray. Residue Tyr32, GppNHp, and GDP are depicted by stick models.

Section 6: Analysis of Reported Ras Structures

Table S1. Structures of Ras proteins

[a] Some PDB files contain more than one Ras structures and they are all included in our study. In the table we only show the data for the first structure in every PDB file.

[b] Distance was calculated between the hydroxyl oxygen atom of Tyr32 and the Cα atom of Gly12. In some structures, Tyr32 was mutated or its side-chain conformation was unresolved, which are denoted as "Mutated" or "No Structure", respectively.

[c] Dihedral was calculated by the Cα atoms of Ile24, Ala66, Glu76 and Val81. In some structures, the involved residues were mutated or their side-chain conformations were unresolved. Instead, their nearby residues are used and some are denoted as "No Structure".

Section 7: Interactions between Thr35 and Gly60 with GTP and GDP
Figure S5. (A) Coupled interaction of Thr35 and Gly60 with the γ-phosphate of GTP (PDB ID: 6GOD). The backbone carbon atoms of Thr35 and Gly60 are colored in blue and the phosphorus atoms of GTP are colored in red. Interactions between Thr35 and Gly60 are depicted by yellow dash lines. **(B)** Uncoupling of Thr35 and Gly60 with GDP after hydrolysis (PDB ID: 4LPK). Ras is shown in gray with the switch I and II domains in pink, and light blue, respectively, and Mg^{2+} ion is displayed by a green sphere. Thr35, Gly60, and GTP/GDP are represented by sticks.

Section 8: Markov State Models (MSMs) Construction

Markov state models (MSMs) were built from our simulation data using MSMBuilder[90,91] following the standard protocol[90,92] (http://msmbuilder.org/3.8.0/). The first step for MSM construction is the transformation of the Cartesian coordinates from the raw simulation data into vector features invariant to translation and rotation. The "AlphaAngleFeaturizer" algorithm in MSMBuilder that extracts alpha (dihedral) angles was applied to the featurization of our simulation data. Then, to capture the slow and important conformation changes and to improve the statistical qualities of our data, dimensionality reduction was carried out using time-structure based independent component analysis (tICA).[93] For our alpha angle structural features, each was transformed into 10 tICA components. Next, the states of the MSM were defined by clustering the interconverting conformations. The "MiniBatchKMeans" algorithm for Mini-Batch K-Means clustering was used to partition the tICA data into clusters. Finally, a 200-microstate MSM with a lag time of 8 ns was created (please see the following section for details) and applied to further study.

Section 9: Validation of the Markovian lagtime for the Ras model

To examine whether our model was Markovian and reliable, we carried out implied timescales analysis. Multiple transition probability matrixes (TPMs), which account for the probabilities of transitions among all microstates, were constructed for different lag times (i.e. time intervals between transitions) and the relaxation timescales or the implied timescale was calculated from Eq. (4):

$$\tau_i = -\frac{\tau}{\ln \lambda_i} \tag{4}$$

where τ is the lag time for the construction of TPM, λ_i is the ith eigenvalue of the TPM, and τ_i represents the implied timescale or the relaxation timescale corresponding to the ith relaxation mode of the system. Markovian property can be demonstrated if τ_i is independent of τ, which can be depicted by a level-off implied timescales plot.

TPMs in MSM were computed with the lag times τ chosen from the set of values with the help of PyEMMA[94]. As shown in Figure S6, our implied timescales test shows that the plot levels off at lag times of 6 ns. Hence, for lag times approximately longer than 6 ns, the models are Markovian. Based on this, we choose a lag time of 8 ns and use it for further analysis. We then lumped our model into 9 macrostates using the Robust Perron Cluster Cluster Analysis (PCCA+) plugin implemented in MSMBuilder package and the resulting model was also demonstrated to be Markovian with Chapman-Kolmogorov test using PyEMMA (Figure S7).

In addition to implied timescales analysis, our MSMs were also tested against our simulation data and the experimental results. The 200-microstate MSM was projected onto the conformational landscape of Ras sampled by MD simulations and the microstates ensemble spanned across the Ras hydrolysis pathway (Figure S8), which indicates that our MSM is a good reflection of the deactivation process in reality. Moreover, all Ras structures reported so far are extracted from PDB and they are also projected onto the Ras deactivation path and their distribution resembles to that of the MSM (Figure S8), which suggests that the computational model is in reasonable agreement with the experimental data. Taken together, these agreements between

theory and experiment highlight the ability of our MSM to reproduce the overall Ras

hydrolysis reaction under study and it is suitable for further investigation.
Figure S6. The implied timescale plots as a function of lag time for the MSMs constructed based on simulations data. The logarithmic convergence of the longest relaxation timescales suggested that the corresponding models were Markovian since the model kinetics were independent of the lagtimes.
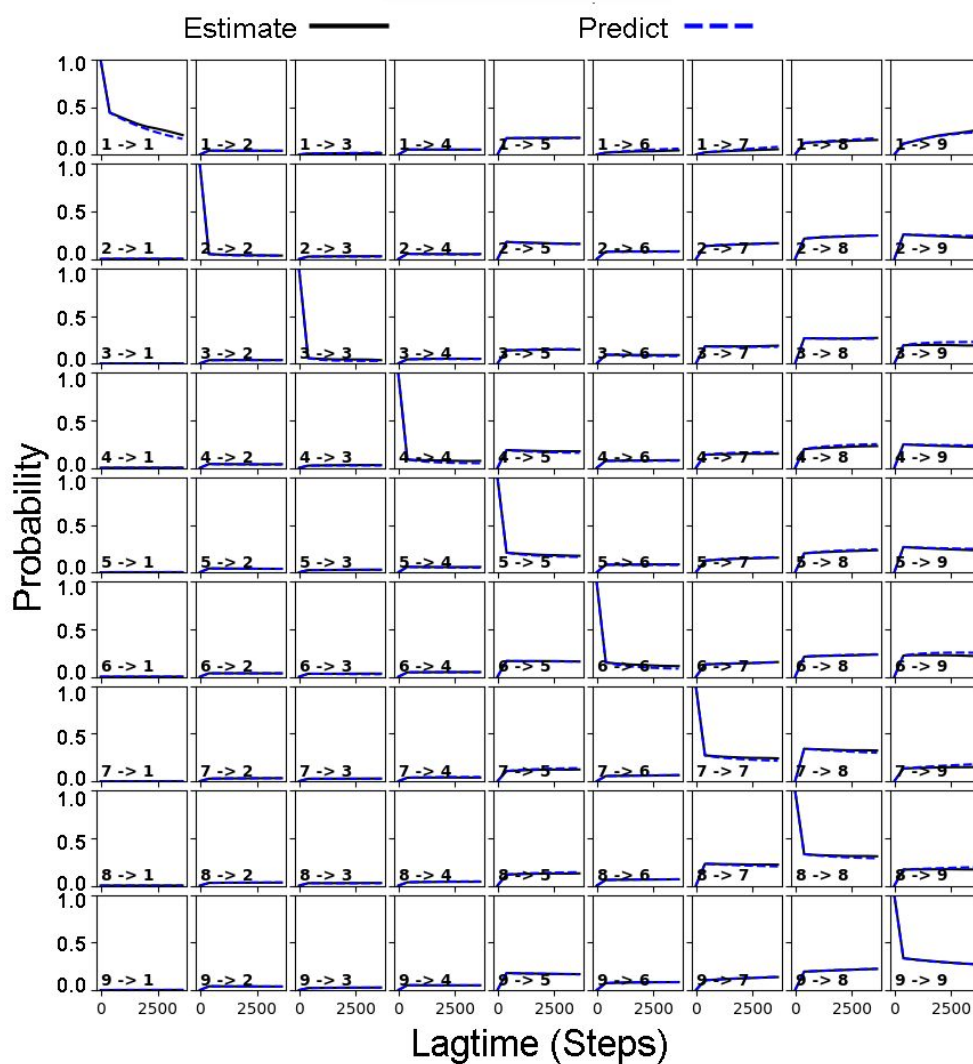

Figure S7. Validation of MSM through Chapman-Kolmogorov test. Shown are data for MSM (black line) and the observed trajectory (blue dotted line, with estimated error).
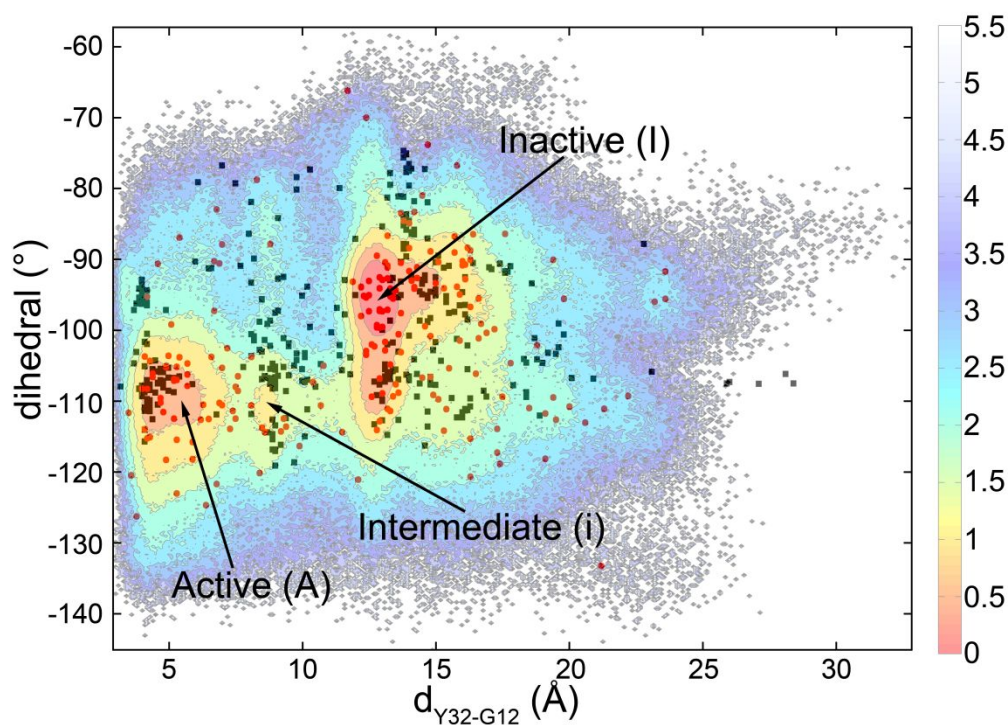

Figure S8. MSM and crystallographic results show similar distributions along the Ras deactivation path. Conformational landscape of the Ras deactivation is mapped by MD simulations. The $d_{Y32\text{-}G12}$ is defined as the distance between hydroxyl oxygen of Tyr32 and Cα of Gly12, and the dihedral is calculated by the Cα of Ile24, Ala66, Glu76 and Val81. Black dots represent the existing crystal structures of Ras and red dots represent MSM microstates.

Section 10: Extraction and Analysis of Representative Substate Structures

Following the standard protocol for time-structure based independent component analysis (tICA) and configurations extraction[90,92], we carried out tICA for our simulation data and MSMs. As shown in Figure S9, our trajectories were projected onto two dominant tICs and the representative substate structures were extracted from the low-free-energy regions and were denoted as S1-S9.

Projection of the representative configurations onto the Ras deactivation pathway shows that they distribute along the reaction path and can cover most of the critical states including the newly revealed intermediate state (Figure 2B). Also, they are tested against the existing crystallography results and they agree well with the closest crystal structures with root mean square deviations (RMSDs) of less than 1 Å (Table S2). Therefore, these results show that our MSM and the MSM-based substates are sufficiently good reflections of reality to carry out further research.
Figure S9. Projection of the MD simulations onto the two dominant modes of the tICA model in MSM analysis. The nine representative configurations, denoted as S1-S9 by red stars, were extracted from the model according to the centroids of the low-free-energy regions.

Table S2. Comparison between the nine MSM substate structures and their closest crystal structures

Substate ID	Distance (Å)[a]	Dihedral (°)[b]	PDB ID	Distance (Å)	Dihedral (°)	RMSD (Å)
S1	4.0	-108.242	5WDP	4.2	-107.637	0.706

[a] distance is calculated between the hydroxyl oxygen atom of Tyr32 and the Cα atom of Gly12.

[b] dihedral is calculated by the Cα atoms of Ile24, Ala66, Glu76 and Val81.

Section 11: Kinetic Properties of Ras Deactivation

We calculated the mean first passage time (MFPT) for our MSM model in an attempt to explore the dynamic hydrolysis pathway. Details for the calculation of MFPTs from given MSMs have been reported by Singhal *et al.* previously[95-96], and here, we employed MSMbuilder package for the calculations.

MFPTs come as products of series or linear equations based on the transition probability matrix of the corresponding MSM model. Within the MSM, they represent the average time it takes to transit from state i to state j. MFPT is defined based on the following equations:

$$MFPT(i) = \sum_{transition(i,k)} Tik \times MFPT(i \,|\, transition(i,k)) \tag{5}$$

$$MFPT(i) = \sum_{edge(i,k)} Tik \times (\tau + MFPT(k)) \tag{6}$$

In equation (5), the sum goes over all transition from state i to state j and *Tik* stands for the probability to transit from state i to state k. In equation (6), the sum goes over all edges starting from state i, and τ stands for the time interval between state i and state j. We can further write equations for MFPT from all states to state j, and by combining these sets of linear equations, we can work out the results for *MFPT(i)*.

Our MSM indicates that the dominant deactivation pathway follows the sequential transitions in the order of S1→S3→S4→S6→S9 (Figure 2B). The kinetics of the deactivation pathway indicates that the transition from the active to inactive states is fast (approximately 600 ns) (Figure S10), which is in line with the relatively small energy barriers between the active, inactive and intermediate states observed in our free energy landscape plot shown in Figure 2A but is inconsistent with the experimental measurement characterized by slow intrinsic rate of GTP hydrolysis[52, 97-98]. However, there is one caveat worth mentioning owing to the different kinetics obtained by the MFPT calculation and the experimental observation. Our initial structures used in simulations obtained from the transition pathway generated by the MEP method have crossed the energy barriers between the conformational state transitions. Because of an extensive set of distinct initial structures of Ras deactivation used in simulations, its conformational landscapes could be rapidly sampled. Similar situation has also been

observed in Src kinase activation[99]. As a result, this factor must presumably affect the kinetics of Ras deactivation.
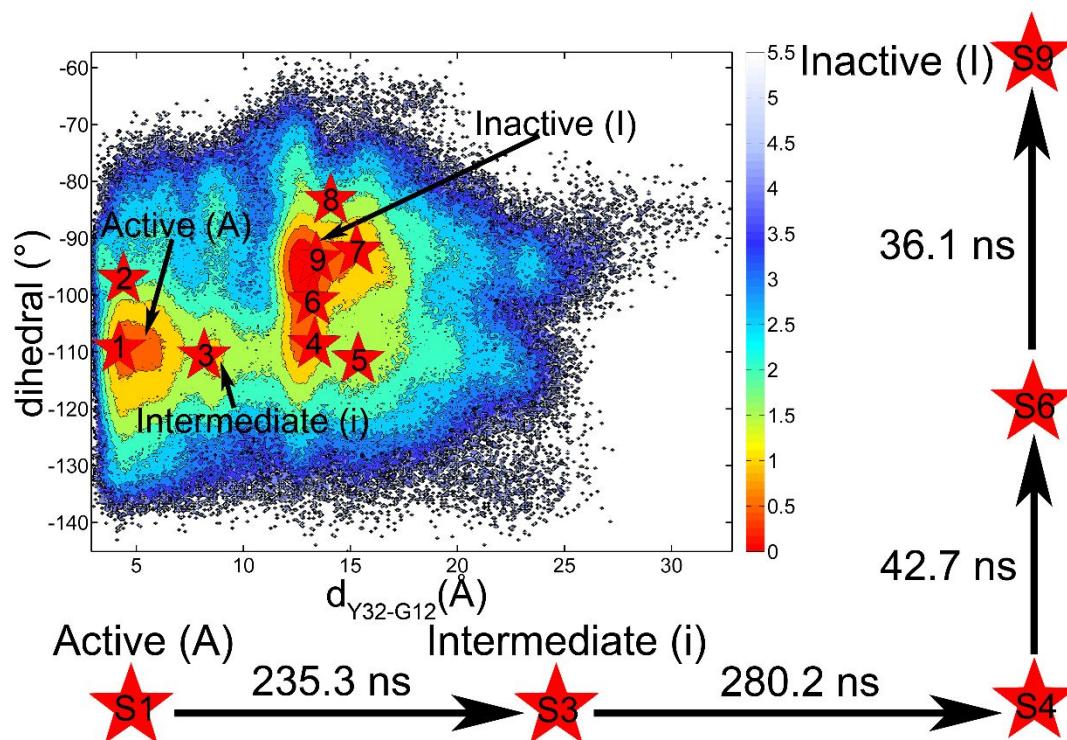

Figure S10. The kinetics transition pathway of Ras from Active state (A) to Inactive state (I) through the major MSM substates (S1→S3→S4→S6→S9), and the MFPTs for the transitions are provided above the arrows.

Section 12: Pocket Detection and Clustering

Fpocket was employed for pocket detection on our MSM substate structures[100,101]. All results were classified and clustered based on their conformations and sequences, yielding four groups designated as P1-P4 (Table S3).

Table S3. Fpocket prediction results and the corresponding classic binding sites on Ras

Fpocket Result	Predicted Sequence	Reported Site	Reported Region	Ligands	Crystal Structure	Pocket Similarity Score	Ref
P1	7-10,16,37,57-59,61-63,68,72,78,92,96,99,103	Switch II Pocket (S-IIP)	α4-helix (87-91), α5-helix (93-104), β1-sheet (3-9), loop 1 (10-15), and Switch II (59-76)	Ras^{G12C}-specific covalent inhibitors	5V9L	0.47493	[19]
P2	5-7,36-40,54-59,66,67,70,71,74-77	Kobe Site	β1-sheet (3-9), β3-sheet (38-46), β4-sheet (49-57), and Switch II (59-76)	DCAI[a], Kobe-family ligands, indole-, sulfonamide-, phenol-containing ligands	2LWI	0.62955	[76]
P3	76-78,100,104-106,108-110,162,163,166	Cyclen Site	α4-helix (87-91), α7-helix (152-167), β6-sheet (104-107), loop 10 (108-110), and loop 7 (74-78)	M^{2+}-cyelen, M^{2+}-bisphenol A[b]	3L8Y	0.58607	[70]
P4	16-21,24,25,29,30-32,34-36,38,40,55,57,59						

[a] DCAI stands for 4,6-dichloro-2-methyl-3-aminoethyl-indole.

[b] M^{2+} stands for bivalent metal ions.

Section 13: Comparison Analysis of Computational and Experimental Pocket Results

In our pocket detection results, P1-P3 were first compared with previous reported classic allosteric sites, Switch II pocket (S-IIP)[1], Kobe site[76], and cyclen site[70] by sequences and structures (Figure 3, Figure S11, Figure S12, and Table S3). Then, APoc (Alignment of Pockets), an algorithm for large-scale structural comparison of protein pockets[102], was applied to analyze the structural similarity of the computationally detected and experimentally determined sites (Table S3). Considering both the sequence and structure similarity and the relatively high Pocket Similarity (PS) scores, our MSM-based prediction outcomes and the existing experimental results can be regarded to be similar.
Figure S11. A. Structure of Kobe site in K-Ras with ligand 0QX inside (PDB ID: 4EPV). K-Ras is gray and Kobe site is highlighted in pink. Ligand 0QX is represented by sticks and colored by element, with the backbone carbon atoms shown in green. **B.** Structure of P2 predicted by MSM-based method. K-Ras is gray and P2 is highlighted in pink.
Figure S12. A. Structure of cyclen site in H-Ras in complex with ligand Zn^{2+}-cyclen (PDB ID: 3L8Y). H-Ras is gray and cyclen site is highlighted in pink. Ligand Zn^{2+}-cyclen is shown by sticks and the carbon atoms are shown in green. **B.** Structure of P3 predicted by MSM-based method. H-Ras is gray and P3 is highlighted in pink.

Section 14: The Dynamic Nature of S-IIP

The conformational transitions of Ras deactivation in our simulations suggest a dynamic nature of the SWII pocket. To test this hypothesis, we superimposed the crystal structures of Ras G12C with covalent inhibitors bound to the allosteric SIIP pocket (Figure S13). This comparison shows the different locations and topology of the SIIP pocket for covalent allosteric inhibitors. The different binding poses of covalent allosteric inhibitors highlight the flexible nature of the SIIP pocket. Therefore, the dynamic nature of the SIIP pocket observed in the simulations is consistent with the experimentally crystallographic studies.
Figure S13. Representative covalent inhibitors bound to the allosteric switch II pocket (SIIP) of Ras^{G12C}. The crystal structure of Ras^{G12C}-compound **6** (carbon colored in pink) (PDB ID: 4NMM) is used as a template, and other crystal structures of K-Ras^{G12C} allele-specific allosteric covalent inhibitors, Ras^{G12C}-3_AM (carbon colored in yellow) (PDB ID: 5V9O), Ras^{G12C}-ARS-853 (carbon colored in light blue) (PDB ID: 5F2E), Ras^{G12C}-ARS-1620 (carbon coloured in cyan) (PDB ID: 5V9U), and Ras^{G12C}-compound **12** (carbon colored in orange) (PDB ID: 6N2K), are aligned to the template. The switch I and II domains and the α3-helix are colored in pink, light blue, and wheat, respectively. The mutated Cys12 and covalent inhibitors are depicted by stick models. The chemical structures of covalent inhibitors, compound **6**, 3_AM, ARS-853, ARS-1620, and compound **12**, are showing with their original sources.

Section 15: Protein-Protein Interactions (PPIs) Analysis for Ras and Comparison with the Newly Detected Pocket

PISA (Proteins, Interfaces, Structures and Assemblies) is a web server for the investigation of macromolecular complexes and structures and it can also provide detailed insights into the protein surfaces, interfaces and assemblies[103]. Here, PISA was applied to the analysis of the PPIs between Ras and its major effectors, Raf (PDB ID: 4G0N)[77], PI3K (PDB ID: 1HE8)[48], and RalGDS (PDB ID: 1LFD)[104]. Residues along the PPI surfaces are revealed and the interaction details are also unveiled. PISA analysis results are compared with P4 and the large overlap between the PPI interfacial residues and P4 implies that this pocket situates along the PPI interfaces, which is consistent with the structural comparisons (Figure 4). Additionally, residues involved in hydrogen bonds or salt bridges formation unraveled by PISA are regarded as hot-spots for PPIs (Figure S14) and most of them (Thr20, Ile21, Gln25, Glu31, Ile36, Asp38, and Ile55 are covered by P4 (Figure S15). Hence, P4 possesses great potential as a drug target for the modulation of the PPIs between Ras and its effector proteins.
Figure S14. Sequence alignment of the residues on H-Ras involved in Ras-Raf, Ras-PI3K, and Ras-RalGDS interactions. Residues on the PPI interfaces are highlighted in red and hot-spot residues are underlined. Residues correspond to P4 are highlighted with red boxes.
Figure S15. Structural overview of the critical residues within the predicted P4 pocket. Overall backbone of K-Ras is colored in gray, computational prediction probe is shown in cyan, and critical residues are displayed in pink.

Section 16: Protein Expression and Purification of K-Ras and GTP Hydrolysis Activity Assay

16.1 Protein Expression and Purification

The full-length human K-Ras4B cDNA was cloned into the pET42a bacterial expression plasmid using the NdeI and XhoI restriction sites, adding an N-terminal 6x histidine tag to ease protein purification as previously described.[105] Plasmid was transformed into *E.coli* Rosetta(DE3) cells for protein purification. The cells were induced with 0.5 mM isopropyl β-D-1-thiogalactopyranoside (IPTG) at 18℃. The protein was firstly purified with nickel column (GE healthcare) in the lysis buffer (50 mM HEPES, pH 7.4, 500 mM NaCl, 2 mM MgCl$_2$, and 20 mM imidazole), 1mM dithiothreitol and protein inhibitor cocktail was added before French Press. Then gel filtration chromatography was last purification step, using a Superdex 75 column (10/ 300 GL) with the following buffer (50 mM Tris-Citrate, pH 6.5, 50 mM NaCl, 5 mM MgCl$_2$, 0.01 mM Guanosine diphosphate and 1 mM dithiothreitol). Purification of mutation forms of K-Ras protein was carried out analogously.

16.2 GTP Hydrolysis Activity Assay

GTP hydrolysis activity was determined by measuring the release of inorganic phosphate from GTP using the EnzChek Phosphate Assay Kit (Invitrogen). The assay medium contained 50 mM Tris-HCl, 1 mM MgCl$_2$, pH 7.5, 0.2 mM 2-amino-6-mercapto-7-methylpurine ribonucleoside, 15 μM K-Ras4B protein, 1.0 units of purine nucleoside phosphorylase. The plate was incubated at room temperature for 10min. Then it was warmed to 37℃ in a microplate reader (BioTek, SYNERGY neo) and added 500 μM GTP to start the reaction. Absorbance was normalized to phosphate standards and initial rates were calculated. Each experiment was independently repeated three times in triplicate.

Section 17: Measurement of Enzymatic Activities by Ten Additional Mutations at the Periphery of the P4 Site

Figure S16: Structural overview of seven critical residues (T20, I21, Q25, E31, I36, D38, and I55) (colored in pink) within the predicted P4 site and ten residues (L23, N26, F28, D30, S39, R41, K42, D54, L56, and T58) (colored in light teal) at the periphery of the P4 site. Overall backbone of K-Ras is colored in gray and computational prediction probe of P4 site is shown in pink.
Figure S17: Mutagenesis experiments. The intrinsic GTP hydrolysis activity of ten Ras variants (L23A, N26A, F28A, D30A, S39A, R41A, K42A, D54A, L56A, and T58A) at the periphery of the P4 site was measured and the relative activities of each mutant are exhibited as a percentage of wild-type enzyme. The wild-type enzyme activity of Ras is represented as 100%. All assays were performed in triplicate, and the results are presented as average ± SD.
