1. General Methods and Experiments ..... S2-S5
2. Synthetic Procedures ..... S6
3. NMR, ESI mass, UV-vis, PL Spectra and Crystal structure
a) NMR spectra of azide/ tetrazole ( $\mathbf{A} / \mathbf{B}$ ) ..... S7
b) NMR and ESI mass- spectra of BtPT ligand ..... S8-S9
c) NMR and ESI mass spectra of Ru-1 ..... S9-S12
d) Normalized absorbance and PL spectra of Ru-1 and Ru-1-OH ..... S12
e) UV-vis selectivity of Ru-1 with ROS, RNS, anions ..... S13
f) UV-vis titration of $\mathbf{R u}-\mathbf{1}$ with $\mathbf{H O C l}$ ..... S14
g) Calculation of detection limit ..... S14-S15
h) Competitive study of ROS/RNS/anions in PL spectroscopy ..... S15
i) Emission Lifetime measurement of $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u - 1 - O H}$ ..... S16
j) pH effect on Ru-1 and Ru-1-OH ..... S16
k) Time course for $\mathbf{R u} \mathbf{- 1}$ in presence of HOCl and PL titration in DMSO ..... S17
1) ESI mass spectrum of $\mathbf{R u} \mathbf{- 1}$ and NaOCl reaction mixture ..... S17
m) NMR and ESI mass spectra of Ru-1-OH ..... S18-S19
n) UV-vis and PL spectra of Ru-2 in presence of $\mathbf{H O C l}$ ..... S20
o) ESI mass spectrum of $\mathbf{R u - 2}$ and NaOCl reaction mixture ..... S21
p) PL titration of BtPT with HOCl ..... S21
q) ${ }^{1} \mathrm{H}$ NMR titration of BtPT ligand with NaOCl ..... S22
r) Normalized absorbance and PL spectra of Ru-3 ..... S22
s) NMR and ESI mass spectra of Ru-3 ..... S23-S24
t) Crystal structure of $\mathbf{R u} \cdot \mathbf{3} \cdot \mathbf{H}_{2} \mathrm{O}$ ..... S24
4. List of selected probes for $\mathrm{HClO} / \mathrm{ClO}^{-}$detection ..... S25-S27
5. X-ray crystallography ..... S27-S30
6. Computational study ..... S31-S41
7. Cell viability study ..... S41
8. References ..... S42

## 1. General Methods and Experiments

## Preparation of ROS and RNS solutions

Generation of $\mathrm{HOCl} / \mathrm{OCl}^{-}$: The source of HOCl was commercial bleach. The concentration of the HOCl stock solution was determined by measuring the absorbance at 235 nm with a molar extinction coefficient of $100 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ in PBS buffer ( $\mathrm{pH}-7.4$ ).

Generation of $\mathrm{H}_{2} \mathrm{O}_{2}$ : The concentration of stock $\mathrm{H}_{2} \mathrm{O}_{2}$ solution was obtained from the absorbance at 240 nm with a molar extinction coefficient of $43.6 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$.

Generation of ${ }^{t} \mathrm{BuOOH}$ : The commercial available tert-Butyl hydroperoxide solution was diluted with double distilled water and used as a source of ${ }^{\mathrm{t}} \mathrm{BuOOH}$.

Generation of $\mathrm{O}_{2}{ }^{-}$: Superoxide radical anion was generated from solid potassium superoxide $\left(\mathrm{KO}_{2}\right)$.

Generation of ${ }^{\circ} \mathrm{OH}$ : Fenton reaction is used for the generation of hydroxyl radical ( ${ }^{\circ} \mathrm{OH}$ ). An aqueous solution of ferrous sulphate was added to 10 times higher concentrated $\mathrm{H}_{2} \mathrm{O}_{2}$ solution and the concentration of ${ }^{\circ} \mathrm{OH}$ was determined as same equivalent to the Fe (II) concentration.

Generation of peroxynitrite ( $\mathrm{ONOO}^{-}$): A mixture of sodium nitrite ( 0.6 M ) and hydrogen peroxide $(0.7 \mathrm{M})$ solution was acidified with hydrochloric acid $(0.6 \mathrm{M})$ and followed by the immediate addition of sodium hydroxide ( 1.5 M ) solution. The resulting solution was kept at lower than $-18{ }^{\circ} \mathrm{C}$. The solution was liquefied instantly before use. The concentration of the stock solution was measured in 0.1 M NaOH by determining the absorbance at 302 nm with a molar extinction coefficient of $1670 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$.

Generation of $N O^{\circ}$ : SNP (Sodium nitroferricyanide (III) dihydrate) was used for generation of nitric oxide.

Generation of singlet oxygen $\left({ }^{1} O_{2}\right):{ }^{1} \mathrm{O}_{2}$ was generated by mixing of 1 mM NaClO with 1 mM $\mathrm{H}_{2} \mathrm{O}_{2}$.

## Calculation of Detection Limit

The detection limit was calculated based on titration data. To determine the $\mathrm{S} / \mathrm{N}$ ratio, the standard deviation of blank solution was calculated with 10 replicate data of Ru-1 without
addition of HOCl in PL spectroscopy. Finally, the detection limit (DL) of $\mathbf{R u} \mathbf{- 1}$ for $\mathbf{H O C l}$ was determined from the following equation.

$$
\mathrm{DL}=3 \sigma / \mathrm{K}
$$

Where $\sigma$ is the standard deviation of the blank solution and K is the slope obtained from the plot of calibration curve.

## Calculation of Quantum Yield

The quantum yield of $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u - 1 - O H}$ were determined in PBS buffer ( $\mathrm{pH} 7.4,10 \mathrm{mM}$, containing $5 \% \mathrm{DMSO}$ ) and $\left[\mathrm{Ru}(\mathrm{bpy})_{3}\right]\left(\mathrm{PF}_{6}\right)_{2}$ was used as a reference $\left(\Phi_{\mathrm{R}}\right.$ of 0.062 in $\left.\mathrm{CH}_{3} \mathrm{CN}\right) .{ }^{[1]}$ The quantum yield is calculated according to the following equation:

$$
\Phi_{S}=\Phi_{R} \times \frac{1-10^{-A_{R}}}{1-10^{-A_{S}}} \times \frac{I_{S}}{I_{R}} \times \frac{\eta_{S}^{2}}{\eta_{R}^{2}}
$$

Where, $\Phi_{S}$ and $\Phi_{R}$ are respective the quantum yields of the sample and reference. $I_{S}$ and $I_{R}$ are represented the area under emission spectra of the sample and the reference respectively. $A_{S}$ and $A_{R}$ are the absorbance of the sample and the reference at the excitation wavelength, respectively. $\eta_{S}$ and $\eta_{R}$ are the refractive index of the solvents used for the sample and reference, respectively.

## Calculation of excited states lifetimes

The luminescence lifetime of $\mathbf{R u - 1}$ before and after addition of HOCl was measured using a time-correlated single photon counting (TCSPC) spectrometer from Lifespec II instrument (Edinburgh Ltd., U.K.). The samples are excited at 470 nm using a picoseconds laser diode. The fluorescence decays were monitored at the corresponding emission maxima as observed in the steady state fluorescence measurement. The data were analysed using FAST decay analysis software from Edinburgh Instruments. All the fluorescence decays were fitted with a biexponential function considering a $\chi^{2}$ value close to 1 , which is an indication of good fitting. Experimental time-resolved luminescence data were calculated using the following multiexponential decay equation

$$
\langle\tau\rangle=\sum \mathrm{a}_{\mathrm{i}} \tau_{\mathrm{i}}
$$

Whereas, $a_{i}$ is the amplitude of the $i^{\text {th }}$ decay component $\left(a_{i}=\alpha_{i} / \Sigma \alpha i\right)$ and $\tau_{i}$ is the excited state luminescence life time of the $\mathrm{i}^{\text {th }}$ component.

## Electrochemical studies

For electrochemical analysis, we have taken the three electrodes cell system, containing a Pt working electrode, a Pt wire auxiliary electrode and an Ag wire as a pseudo-reference electrode. Experiments were carried out on a 1.0 mM of $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u} \mathbf{- 1 - O H}$ solutions in a dry and degassed acetonitrile with 0.1 M tetra-n-butylammonium perchlorate $\left(\mathrm{Bu}_{4} \mathrm{NClO}_{4}\right)$ as the supporting electrolyte. To compare the oxidation potential shift between $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u} \mathbf{- 1} \mathbf{-}$ $\mathbf{O H}$, the cyclic voltammetry data of $\left[\mathrm{Ru}(\mathrm{phen})_{3}\right]\left(\mathrm{PF}_{6}\right)_{2}$ was also collected under the same experimental conditions. After each experiment, the electrochemical potential window was calibrated using ferrocence as the internal standard. The redox potential of the ferrocene/ferrocenium $\left(\mathrm{Fc} / \mathrm{Fc}^{+}\right)$couple was taken as +0.400 V vs Ag wire electrode. ${ }^{[2]}$ All the reported potentials were measured at a scan rate of $100 \mathrm{mV} \mathrm{s}^{-1}$.

## Computational Studies

The geometry optimization of $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u - 1 - 0} \mathbf{O}^{-}$(deprotonated form in solution) were performed with the Gaussian 09 program package, using density functional theory (DFT). The B3LYP/6-31G $(\mathrm{d}, \mathrm{p})^{[3]}$ basis set was used for $\mathrm{C}, \mathrm{H}, \mathrm{N}, \mathrm{O}, \mathrm{S}$ together with the LANL2DZ ${ }^{[4]}$ for ruthenium. The geometry was fully optimized in the ground states. Time dependent density functional theory (TD-DFT) calculations using the polarizable continuum model (PCM) ${ }^{[5]}$ non equilibrium version were performed with a spin-restricted formalism to examine low-energy excitations at the ground-state geometry in water at the same level of calculation, as employed for geometry optimizations. The triplet states TDDFT calculations using the optimized triplet state geometry at the same level [B3LYP/6-31G (d,p)] associated with the $\mathrm{PCM}\left(\mathrm{H}_{2} \mathrm{O}\right)$ were employed for singlet-triplet transitions to study the nature of the non-emissive and emissive states of $\mathbf{R u} \mathbf{- 1}$ and $\mathbf{R u - 1}-\mathbf{O}^{-}$, respectively.

## Cytotoxicity Study

The Cytotoxicity test of the Ru-1 against HEK-293T cells was determined by MTT assay as described by Mosmann, (1983) in a 96-well cell culture plate. The cells were seeded in a 96well plate containing 2 ml of DMEM (Dulbecco's Modified Eagle Medium) at a density of 4 $\times 10^{3}$ cells/well and incubated at $37{ }^{\circ} \mathrm{C}, 5 \% \mathrm{CO}_{2}$ incubator. Cells were treated with different concentration of $\mathbf{R u - 1}(0,10,25,50$, and $100 \mu \mathrm{M})$ at $70 \%$ confluency and incubated for 24 h . After incubation in media, the old media was replaced by same volume of serum free DMEM media and MTT salt was added in medium to a final concentration of $0.5 \mathrm{mg} / \mathrm{ml}$. The plate was incubated for 4 hours at $37{ }^{\circ} \mathrm{C}$ until intracellular purple formazan crystals were visible
under microscope. After incubation, the media was discarded and $200 \mu \mathrm{l}$ of DMSO was added in well. The absorbance change was monitored at 570 nm using iMark ${ }^{\text {TM }}$ (Bio-Rad, USA) microplate absorbance reader. Readings were taken in triplicate and the $\%$ cell viability was calculated for samples and controls based on the following formula:

$$
\% \text { cell viability }=\left(\mathrm{R}_{\text {sample }}-\mathrm{R}_{0}\right) /\left(\mathrm{R}_{\text {ctrl }}-\mathrm{R}_{0}\right) \times 100
$$

Where, $\mathrm{R}_{\text {sample }}$ is the absorbance in the presence of $\mathbf{R u} \mathbf{- 1} \mathbf{R}_{\text {ctrl }}$ is the absorbance of in the absence of the sample (vehicle control). $\mathrm{R}_{0}$ is the averaged background (noncell control) absorbance.

## Cell culture and Exogenous and Endogenous HOCl Imaging

Cells were seeded at normal confluency ( $\sim 10 \%$ ) in 12 well sterile culture plates on poly-llysine coated coverslips containing 2 ml of DMEM (Dulbecco's Modified Eagle Medium) medium and incubated inside a $\mathrm{CO}_{2}$ incubator at $37{ }^{\circ} \mathrm{C}$ with $5 \% \mathrm{CO}_{2}$ supplemented with $1 \%$ streptomycin penicillin and $10 \%$ FBS (Fetal Bovine Serum). When the cells were approximately $70 \%$ confluent, the media was replaced with fresh media.

For the control experiment, the cells were only treated with $\mathbf{R u} \mathbf{- 1}(50 \mu \mathrm{M})$ for 15 min . For the imaging of the exogenous HOCl, the HEK293T cells were incubated with Ru-1 (50 $\mu \mathrm{M}, 15 \mathrm{~min})$ and then treated with aqueous $\mathrm{NaOCl}(50 \mu \mathrm{M}, 15 \mathrm{~min})$. For the detection of endogenously produced HOCl , the HEK293T cells were treated with lipopolysaccharide (LPS, $1 \mu \mathrm{~g} / \mathrm{ml})^{[6]}$ and kept under incubation for 2 h . Then, the cells were treated with Ru-1 ( $25 \mu \mathrm{M}, 15 \mathrm{~min}$ ). Similarly, to determine the paraquat-stimulated endogenously generated $\mathbf{H O C l}$, the cells were treated with paraquat ( 1 mM ) for 1.5 h and subsequent addition of $\mathbf{R u - 1}$ $(25 \mu \mathrm{M})$ for another 15 min . After the all treatment finally the cells were washed two times with $500 \mu \mathrm{l}$ of HBSS (Hank's Balanced Salt Solution) and fixed with chilled absolute ethanol. The fixed cells were washed further three times with $500 \mu \mathrm{l}$ of HBSS to remove residual ethanol. Finally, the cell containing coverslips were mounted on glass slides. Imaging studies of these three experiments were performed by conducting fixed-cells imaging on confocal laser scanning microscopy (Leica, TCS SP5, Germany). Nucleus staining dye DAPI was used in all experiments. Images were taken using 405 nm (for DAPI) and 488 nm (Ru-1) excitation and emission windows of 420-510 nm (blue) and 510-630 nm (red). Cross- talk of fluorochromes was excluded by the use of the acous to optical tunable filter.

## 2. Synthetic Procedures

## Synthesis of [Bis(1,10-phenanthroline)(2-(1-methyl-1H-1,2,3-triazol-4-yl)pyridine)] ruthenium(II) dihexafluorophosphate], Ru-2.

The control probe Ru-2 was synthesized following the reported literature procedure. ${ }^{[7]}$

## Synthesis of [Bis(1,10-phenanthroline)(2-pyridinecarboxylate)]ruthenium(II) dihexafluorophosphate, Ru-3

The complex Ru-1 ( $0.07 \mathrm{mmol}, 0.073 \mathrm{~g}$ ) was dissolved in $1: 1$ acetonitrile/water mixture (10 $\mathrm{ml})$. To this stirred solution, an aqueous $\mathrm{NaOCl}(7 \mathrm{mmol}, 30 \mathrm{ml})$ was added dropwise. After 24 h stirring, the organic solvent was evaporated and treated with an excess $\mathrm{NH}_{4} \mathrm{PF}_{6}$. The crude precipitate was then purified by silica gel column chromatography $(0.2 \%$ saturated $\mathrm{KNO}_{3}: 9.8 \% \mathrm{H}_{2} \mathrm{O}: 90 \% \mathrm{CH}_{3} \mathrm{CN}$ as an eluent) to afford dark red coloured $\mathbf{R u} \mathbf{- 3}$ in a good

Scheme S1. Synthetic approach to Ru-3 complex
yield ( $0.031 \mathrm{~g}, 60 \%$ ) (Scheme S1). The diffraction-quality single crystals of complex Ru-3 were obtained from an acetone and water (2:1) mixture after five days. Anal. ## 5. X-ray Crystallography

The X-ray data of Ru-1 and Ru-3 were collected at 293 K with Agilent Xcalibur (Eos, Gemini) diffractometer using graphite-monochromated $\mathrm{Mo} \mathrm{K} \alpha$ radiation ( $\lambda=0.71073 \AA$ ). For both complex the data was collected, reduced and cell refinement was done in CrysAlis PRO (Agilent, 2013) software. ${ }^{[9]}$ For both the complexes, $\mathbf{R u}-\mathbf{1} \cdot \mathbf{2 C H C l} 3$ and $\mathbf{R u}-\mathbf{3} \cdot \mathbf{H}_{2} \mathbf{O}$, the absorption was corrected by SCALE3 ABSPACK multi-scan method in CrysAlisPro. The structures of $\mathbf{R u}-\mathbf{1 \cdot 2} \mathbf{C H C l}_{\mathbf{3}}$ and $\mathbf{R u - 3 \cdot} \mathbf{H}_{\mathbf{2}} \mathbf{O}$ were solved by direct methods using the program SHELXS-97 ${ }^{[10]}$ and SIR92 ${ }^{[11]}$ respectively and refined by full matrix least-squares calculations ( $\mathrm{F}^{2}$ ) by using the SHELXL-2014/2017 software ${ }^{[12]}$ within the WinGX ${ }^{[13]}$ environment. All non-H atoms were refined anisotropically against $\mathrm{F}^{2}$ for all reflections. All hydrogen atoms were placed at their calculated positions and refined isotropically. Crystal data collection and refinement details, selected bond lengths and angles for $\mathbf{R u} \mathbf{- 1 \cdot 2} \mathbf{C H C l} 3$ and $\mathbf{R u} \mathbf{- 3} \cdot \mathbf{H}_{2} \mathbf{O}$ are given in Table S 2 to Table S4 respectively. The .cif file was deposited with the Cambridge Crystallographic Data Centre, and the following code was allocated: CCDC- 1497233, and 1831199 for $\mathbf{R u - 1 \cdot 2} \mathbf{C H C l}_{\mathbf{3}}$ and $\mathbf{R u - 3} \mathbf{- \mathbf { H } _ { \mathbf { 2 } } \mathbf { O }}$ respectively. This data can be obtained free of charge via the Internet: www.ccdc.cam.ac.uk/ data_request/cif.

## 6. Computational Study.

Density functional theory (DFT) and time dependant-density functional theory (TD-DFT) calculations (Table S5-S10) were performed to obtain insight into the electronic transitions responsible for the absorption spectra and luminescence spectra of $\mathbf{R u - 1}$ and $\mathbf{R u - 1 - O H}$. It is expected that the $\mathbf{R u - 1} \mathbf{- O H}$ in $\mathbf{9 5 \%}$ aqueous buffer solution exists as enolate, so the deprotonated form, Ru-1-0 ${ }^{-}$was used for all computation. The singlet state TD-DFT calculations in water reflect that the highest and lowest lying MOs present in both $\mathbf{R u - 1}$ (HOMO, HOMO-1, HOMO-2 and LUMO, LUMO+1, LUMO+2, LUMO+3) (Figure S39) and Ru-1-O ${ }^{-}$(HOMO, HOMO-1, HOMO-2, HOMO-3 and LUMO, LUMO+2, LUMO+3, LUMO+4) (Figure S40) contribute major impact on metal-to-ligand charge-transfer ( ${ }^{1}$ MLCT) bands which were observed experimentally at $\lambda_{\max }=400$ and 433 nm . The HOMOs of Ru-1 are mainly located on ruthenium(II) center, whereas, in $\mathbf{R u}-\mathbf{1 - 0} \mathbf{O}^{-}$, HOMOs are situated on ruthenium(II) and partially on hydroxylated BtPT ligand (HOMO, HOMO-1, HOMO-3) (Figure S41-S42). The unoccupied molecular orbitals, LUMO, LUMO+2 and LUMO+3 of Ru-1 correspond to ancillary phen ligand, whereas LUMO+1 correspond to BtPT ligand. Similarly, in the case of hydroxylated product, Ru-1-O $\mathbf{O}^{-}$, the three unoccupied orbitals, LUMO, LUMO+2, and LUMO+3 correspond to ancillary phen ligand (Figure S41-S42). The TD-DFT calculations for Ru-1 indicate that the experimental ${ }^{1}$ MLCT absorption band at $\sim 400 \mathrm{~nm}(3.10 \mathrm{eV})$ arises from strong transitions characterized as HOMO-2 $\rightarrow$ LUMO +1 , HOMO- $1 \rightarrow$ LUMO +1 , HOMO- $1 \rightarrow$ LUMO+2 and $\mathrm{HOMO} \rightarrow$ LUMO $+3(f=0.20$ ) (380.15 $\mathrm{nm}, 3.26 \mathrm{eV})$. The low energy electronic absorption band at $\sim 433 \mathrm{~nm}(2.86 \mathrm{eV})$ in the visible range are assigned to transitions HOMO- $2 \rightarrow$ LUMO, HOMO- $2 \rightarrow$ LUMO +1 , HOMO- $2 \rightarrow$ $\mathrm{LUMO}+2, \mathrm{HOMO} \rightarrow \mathrm{LUMO}+2$ and $\mathrm{HOMO} \rightarrow \mathrm{LUMO}+3(f=0.12)(397.60 \mathrm{~nm}, 3.12 \mathrm{eV})$ (Figure S41 and Table S8). In $\mathbf{R u - 1 - \mathbf { O } ^ { - }}$, the calculated strong transition at $385.9 \mathrm{~nm}(3.21$ eV ), which is due to the $\mathrm{HOMO}-3 \rightarrow \mathrm{LUMO}+3$, HOMO- $2 \rightarrow \mathrm{LUMO}+2$ and HOMO$2 \rightarrow$ LUMO +3 transitions $(f=0.15)$, is assigned to the experimental absorption band at $\sim 400$ nm . Whereas, the experimental absorption band at $\sim 433 \mathrm{~nm}$ corresponds to calculated HOMO- $3 \rightarrow$ LUMO, HOMO- $2 \rightarrow$ LUMO, HOMO- $1 \rightarrow$ LUMO +2 and HOMO- $1 \rightarrow$ LUMO +3 transitions ( $404.9 \mathrm{~nm} ; 3.06 \mathrm{eV}$ ) (Table S9 and Figure S42). The optimized ground states geometries from DFT calculation shows that the highest occupied MOs of Ru-1 (HOMO, HOMO-2) and Ru-1-O ${ }^{-}$(HOMO, HOMO-4) are mainly $d \pi \mathrm{~L} \pi$ and $\mathrm{Ru}\left(\mathrm{dz}^{2}\right)$ in character (Figure 6a, S36-S38). Whereas, the lowest lying MOs of Ru-1 and Ru-1-O ${ }^{-}$are centred at the $\mathrm{L} \pi^{*}$ orbital of phenanthroline ligand. After HOCl stimulated hydroxylation of BtPT ligand,
the metal based $\left(\mathrm{dz}^{2}\right)$ HOMO-4 $(-8.35 \mathrm{eV})$ of $\mathbf{R u} \mathbf{- 1 - 0} \mathbf{O}^{-}$is destabilized by 2.53 eV compared to $d \mathrm{z}^{2}$ based HOMO-2 (-10.88 eV) of Ru-1. Whereas, the d $\sigma^{*}$ orbital of Ru-1-O $\mathbf{O}^{-}$(LUMO+11; $E=-2.48 \mathrm{eV}$ ) is destabilized compared to the d $\sigma^{*}$ orbital of $\mathbf{R u}-\mathbf{1}(L U M O+9 ; E=-5.08 \mathrm{eV})$. Additionally, in $\mathbf{R u - 1 - 0} \mathbf{O}^{-}$, the phenanthroline ligand based LUMO ( $\mathrm{L} \pi *$ ) is destabilized by 2.17 eV which indicates stabilization of ${ }^{1} \mathrm{MLCT}$ and destabilization of ${ }^{1} \mathrm{MC}$ after HOCl promoted hydroxylation, inhibits the thermally accessible non-radiative deactivation between MLCT and MC states found in case of Ru-1 (Figure 6a).

[^0]Table S10. Selected Triplet Excited States of probe Ru-1 and Ru-1-O $\mathbf{O}^{-}$computed by TDDFT at the Optimized Triplet State Geometries.

| Complex | Experimentally <br> observed <br> emission <br> energy <br> [eV(nm)] | Computed <br> vertical <br> excitation <br> transition <br> $[\mathrm{eV}(\mathrm{nm})]$ | $\boldsymbol{f}^{a}$ | Transition | Assignment |
| :--- | :--- | :--- | :--- | :--- | :--- | $\mathbf{C l}^{b}$

$f^{a}=$ oscillator strength, $\mathbf{C I}^{b}$ coefficients are in absolute values;

## 7. Cell viability study and Endogenous HOCl imaging.

Figure S43. Cell viability was assayed by MTT test with different concentration of Ru-1 (A: $0 \mu \mathrm{M}$; B: $10 \mu \mathrm{M}, \mathrm{C}: 25 \mu \mathrm{M}$; D: $50 \mu \mathrm{M}$; E: $100 \mu \mathrm{M}$ ) in HEK-293T cells. Results are reported as mean $\pm$ standard deviation of three independent experiments.
