SHAPE is a program for the stereochemical analysis of molecular fragments and geometries. It calculates continuous shape measures of a set of points (e.g. atomic positions) relative to the vertices of ideal polygons or polyhedral, either centered or non-centered. In addition, it also calculates deviations from minimal distortion paths and polyhedral interconversion generalized coordinates. For more information see the following references:

X-ray diffraction. At first, a crystal of $\mathbf{1}$ was mounted on the diffractometer at 100 K under a cold nitrogen gas stream supplied by an Oxford Cryostream. However, preliminary data collection showed multi-twinning and crystal cracking. Therefore a new crystal was coated in perfluoropolyalkylether oil $(1800 \mathrm{cSt})$ and mounted on a thin quartz fiber attached to a copper pin at room temperature and slowly cooled to 230 K . Data collection were performed at this temperature. Upon father cooling to 80 K the crystal cracked and data obtained at this temperature were not suitable for publication. The same procedure was applied to complex $\mathbf{2}$; in this case crystal did not crack and it was possible to obtain diffraction data at 100 K .

Fig. S3. Comparison between fit results (solid lines) of the susceptibility and magnetization data (insets) of 2 for the "1-J+1-D" model (top) and the " $2-J+2-D$ " model (bottom), respectively. Note that, when adopting the " $1-J+1-D$ " model, the intermolecular interaction term $z J^{\prime}$ is needed to account for the $\chi_{m} T$ decrease at the lowest temperatures.

Fig. S4. Comparison between fit results (solid lines) of the susceptibility and magnetization data (insets) of 2 for the " $2-J+1-D$ " model (top) and the " $2-J+2-D$ " model (bottom), respectively. Note that, when adopting the " $2-J+1-D$ " model, the intermolecular interaction term $z J^{\prime}$ is needed to account for the $\chi_{m} T$ decrease at the lowest temperatures.

Fig. S5. FTIR-ATR spectra of 1 and 2 in the $4000-440 \mathrm{~cm}^{-1}$ range (on a microcrystalline sample).

Fig. S6. Powder XRD ( Cu source) diagrams' comparison between the experimental and theoretical patterns for complexes $\mathbf{1}$ (top) and $\mathbf{2}$ (bottom) in the $3-30^{\circ} 2 \theta$ range. The difference
in the peaks' intensity is probably due to partial decomposition of the crystals caused by loosing of solvate molecules.

Table S2. Crystallographic data for complexes 1 and 2.
