Calculation.

Gravimetric capacitance, C_g (F g⁻¹), of the working electrode can be calculated from the CV curves by using the following equation:

$$C_g = \int I dV / (2 m s \Delta V), \quad (S1)$$

where I (A) is the response current of the CV curve, s (V s⁻¹) is the scan rate, ΔV (V) is the potential window and m (g) is the mass loaded in working electrode.

Volumetric capacitance, C_v (F cm⁻³), of the working electrode can be also calculated from the CV curves by using the following equation:

$$C_v = \int I dV / (2 V s \Delta V), \quad (S2)$$

where V (cm³) is the volume of the film in working electrode.

Gravimetric capacitance, $C_{g,cell}$ (F g⁻¹), of the symmetric supercapacitors can be calculated from the CV curves by using the following equation:

$$C_{g,cell} = \int I dV / (2 m s \Delta V), \quad (S3)$$

where I (A) is the response current of the CV curves, s (V s⁻¹) is the scan rate, ΔV (V) is the potential window and m (g) is the total mass loaded in two electrodes.

Volumetric capacitance, $C_{v,cell}$ (F cm⁻³), of the symmetric supercapacitors can be calculated from the CV curves by using the following equation:

$$C_{v,cell} = \int I dV / (2 V s \Delta V), \quad (S4)$$

where V (cm³) is the total volume of the films in two electrodes.

Energy density, E (Wh L⁻¹ or Wh kg⁻¹), and power density, P (W L⁻¹ or W kg⁻¹), of the symmetric supercapacitors can be calculated according to the following equations:

$$E_g = \int V(t) I dt / M \quad (S5)$$

$$E_v = \int V(t) I dt / V \quad (S6)$$

$$P = 3600 E / \Delta t, \quad (S7)$$

where $V(t)$ (V) is the discharge voltage excluding the IR drop, i is the current (A), M and V are total mass and volume of the active materials (cathode and anode), respectively.

Testing of the working potentials of the negative and positive electrodes vs. Hg/Hg₂SO₄ electrode

The working voltage ranges of the negative electrode were measured with the two-electrode configuration in 3 M H₂SO₄ at room temperature. A multimeter was connected to the negative electrode and the reference electrode (Hg/Hg₂SO₄ electrode) to measure the potential of the negative electrode vs. the reference electrode, when the cyclic voltammetry was tested at different scan rates. Therefore, the potential of the positive electrode vs. the reference electrode can be obtained with the voltage between the positive electrode and the negative electrode is 1 V.

Materials

Unless otherwise indicated, all the chemicals (analytical grade) were from Shanghai Aladdin Biochemical Polytron Technologies Inc, China.

Synthesis of Ti_3AlC_2 powders

Firstly, the mixed powders of TiC (2-4 μm , 99%, Aladdin), Al (1-3 μm , 99.5%, Aladdin) and Ti (≤ 48 μm , 99.99%, Aladdin), with a molar ratio of 2:1.2:1, were ball-milled in absolute ethyl alcohol for 4 h at a speed of 350 rpm. Then, the mixture was sintered at 1400 $^{\circ}\text{C}$ for 2 h in Ar atmosphere. Finally, the sintered product was further ground to obtain fine powders, which were then sieved through a 400 mesh screen.

Materials characterization

Microstructure and elemental composition of the samples were characterized by using field-emission scanning electron microscopy (FE-SEM, Hitachi S-4800), equipped with energy-dispersive X-ray analysis (EDAX) (Hiroba). The morphological properties of the samples were observed by using transmission electron microscopy (TEM, FEI company Tecnai G220 S-twin, 200 kV). X-ray diffraction (XRD) patterns of the samples were recorded by using a Rigaku D/max 2200pc diffractometer, with Cu $K\alpha$ radiation of wavelength $\lambda = 0.15418$ nm, at 40 kV and 40 mA. X-ray photoelectron spectroscopy (XPS) measurements of the samples were fulfilled by utilizing a Thermo Fisher ESCALAB Xi⁺ with an exciting source of Al $K\alpha$.

Table S1 Working potential ranges for the positive and negative electrodes at different scan rates.

Scan rate (mV s ⁻¹)	Potential range for the positive electrode (V vs. Hg/Hg ₂ SO ₄)	Absolute potential for the positive electrode (V)	Potential range for the negative electrode (V vs. Hg/Hg ₂ SO ₄)	Absolute potential for the negative electrode (V)
2	-0.702 ~ -0.108	0.594	-1.108 ~ -0.702	0.406
5	-0.715 ~ -0.105	0.61	-1.105 ~ -0.715	0.39
10	-0.720 ~ -0.100	0.62	-1.100 ~ -0.100	0.38
20	-0.720 ~ -0.080	0.64	-1.080 ~ -0.720	0.36
50	-0.720 ~ -0.070	0.65	-1.070 ~ -0.720	0.35

As shown in Table S1, the working potential ranges for the positive and negative electrodes show a unsteady from 2 to 50 mV s⁻¹, which were derived from the modified two-electrode systems in the H₂SO₄ electrolyte. As a result, this observation is not contradictory to the conclusion that the specific capacitance of the negative electrode is much higher than that of the positive electrode in the MXene based symmetric SCs. Therefore, the specific capacitances at 2, 5, 10, 20 and 50 mV s⁻¹ of the negative electrode are not in full agreement with the expected values, as those presented in Fig. 2f of the manuscript.

Table S2. The resistance for the cell in different electrolytes.

Resistance Electrolyte	Rs ($\Omega \text{ cm}^2$)	Rct ($\Omega \text{ cm}^2$)
3 M H ₂ SO ₄	0.50	1.0
3 M H ₂ SO ₄ + 0.2 M KI	0.52	1.6

Fig. S17

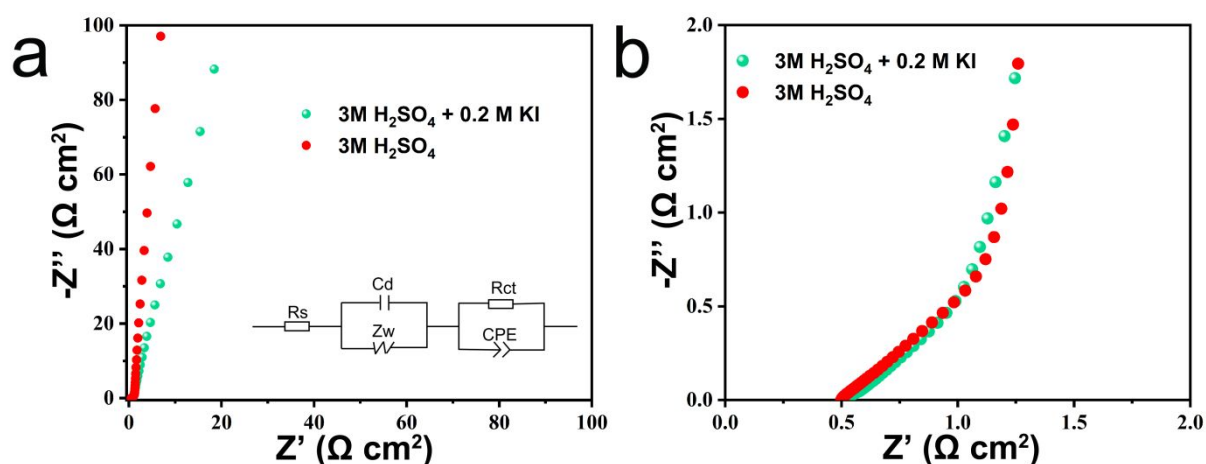

Fig. S17. (a) Nyquist plots of the $\text{Ti}_3\text{C}_2\text{T}_x$ film based cells in 3 M H_2SO_4 and 3 M $\text{H}_2\text{SO}_4 + 0.2 \text{ M KI}$ electrolytes and its electrical equivalent circuit. (b) Magnified high-frequency region of the Nyquist plots.

The internal resistance (R_s) is 0.50 and 0.52 $\Omega \text{ cm}^2$ for the cell in 3 M H_2SO_4 and 3 M $\text{H}_2\text{SO}_4 + 0.2 \text{ M KI}$ electrolytes, which prove that the introduction of KI almost has no effect on R_s . At the same time, the charge transfer resistance (R_{ct}) is 1.0 and 1.6 $\Omega \text{ cm}^2$ for the cell in 3 M H_2SO_4 and 3 M $\text{H}_2\text{SO}_4 + 0.2 \text{ M KI}$ electrolytes, in which the higher R_{ct} is absorbed to the charge transfer progress of I^-/I_3^- .
