Authors contribution

H.M.R. designed the research, performed the UHPLC-PDA and UHPLC-HRMS/MS analyses, processed the data, wrote the manuscript, and revised the manuscript. P.C.P.B. Assisted in the validation procedure, wrote the manuscript, and revised the manuscript. A.B. Assisted in the MS/MS data analysis, wrote the manuscript, and revised the manuscript. R.F.A. provided the plant material, identified the species, and revised the manuscript. P.C.D. provided consultation on the manuscript elaboration and revised the manuscript. A.J.C. designed the research and revised the manuscript. V.S.B. designed the research, acquired funding, and revised the manuscript. All authors have approved to the final version of the manuscript.

Figure S1. Workflow followed for chromatographic method development. (a) The QbD software created and exported the methods needed for the method development directly to the UHPLC software. The chromatograms are processed and the selected responses (for instance, number of total peaks, number of peaks with high resolution and low tailing) are imported back to the QbD software, which provides the statistical analyses for the responses selected (such as the Analysis of Variance, mathematical equations and surface response). (b) Three main steps were followed in the chromatographic method development: screening, optimization and robustness simulator. The designs, variables chosen, and fixed parameters are described. (c) Chromatograms with the higher responses obtained for the RSMS sample for each step are shown (275 nm), such as the conditions employed.....6

Flores), Pink - Ptilochaetoid clade represented by the species *Ptilochaeta densiflora* (photograph by R.F. Almeida), Light Green - Bunchosiod clade represented by the species *Bunchosia maritima* (photograph by J.M.Braga), Purple - Hiraeoid clade represented by the species *Hiraea restingae* (photograph by R.F. Almeida), Dark Green - Tetrapteroid clade represented by the species *Niedenzuella multiglandulosa* (photograph by N. Carvalho, Yellow - Stigmaphylloid clade represented by the species *Banisteriopsis laevifolia* (photograph by C.F. Hall), and Dark Blue - Malpighioid clade represented by the species *Amorimia septentrionalis* (photograph by M.O.O. Pellegrini) (phylogenetic classification according to Davis and Anderson 2010).

S15. Method validation

Specificity

Specificity is the ability to the method to unequivocally assess and differentiate the analyte signals from potential compounds such as impurities, other matrix components or degradants, among others. In the present study, it was determined through the injection of the solvent solution containing only the internal standard (blank), the standards solution and the RSMS solution (n=3). Peaks retention times and resolution of (+)-catechin, (–)-epicatechin, ecdysterone and rutin present in the standard and sample solutions were used to calculate the relative standard deviation (RSD). In addition, the mass spectra of each compound present in both standard and RSMS solutions were recorded and used to confirm the specificity and identity of the peaks.

The detected peaks corresponded to (+)-catechin (4.88 min), (–)-epicatechin (6.25 min), ecdysterone (10.61 min) and rutin (11.56 min) in the RSMS solution, showed good resolutions (5.38, 1.98, 7.71 and 1.25, respectively) and did not show any interferences when compared to the standard solution. Moreover, the recorded mass spectra allowed the confirmation of each compound's identity.

Precision (repeatability and intermediate precision)

The precision was estimated by the analysis of six RSMS solutions, each one injected once (n=6). Repeatability (or intraday precision) was expressed as the RSD of (+)-catechin, (–)-epicatechin, ecdysterone and rutin amounts (concentration of injection, $\mu\text{g mL}^{-1}$) measured in two consecutive days. For the first day, the average concentrations measured for (+)-catechin, (–)-epicatechin, ecdysterone and rutin were 10.101, 13.644, 52.377 and 23.672 $\mu\text{g mL}^{-1}$, respectively. For the second day, the average concentrations measured for (+)-catechin, (–)-epicatechin, ecdysterone and rutin were 10.446, 13.829, 52.545 and

23.605 $\mu\text{g mL}^{-1}$, respectively. For intermediate precision, the results of the two days were compared through F-test.

In both days, the RSDs determined for all compounds were lower than 1% (Table 1). The intermediate precision, calculated by the F-test between the two different days, was also very satisfactory since no significant difference at $F = 0.05$ ($n=6-1$) was detected.

Linearity

To determine the linearity of the method at the PDA detector, the calibration curves were prepared in the concentration range expected for each compound in RSMS. It was determined by elaborating calibration curves of each compound ranging from 2.2 to 278% of the working standards concentrations ($n=3$). Internal standardization was also used to improve method confidence. For that, a stock standard solution containing (+)-catechin (100 $\mu\text{g mL}^{-1}$), (-)-epicatechin (150 $\mu\text{g mL}^{-1}$), ecdysterone (776 $\mu\text{g mL}^{-1}$), and rutin (300 $\mu\text{g mL}^{-1}$) in MeOH/H₂O 1:1, was prepared for simultaneous acquisition of the analytical curves. From the stock solution, eleven concentration levels for each compound were prepared (in MeOH/H₂O 1:1), ranging from (i) 0.2 to 25 $\mu\text{g mL}^{-1}$ for (+)-catechin, (ii) 0.3 to 37.5 $\mu\text{g mL}^{-1}$ for (-)-epicatechin, (iii) 1.6 to 194 $\mu\text{g mL}^{-1}$ for ecdysterone, and (iv) 0.6 to 75 $\mu\text{g mL}^{-1}$ for rutin. All solutions contained the internal standard sodium diclofenac at 15 $\mu\text{g mL}^{-1}$. Each calibration concentration sample was injected in three replicates. The linearity was calculated based on the analytical curves built with the nominal concentration of each calibration point and the corresponded average values of the ratios between the area of each calibration point divided by the area of the internal standard ($R = A_{\text{compound}}/A_{\text{IS}}$). The results were interpreted in function of the correlation coefficients (R) calculated for each compound.

The linear ranges of concentrations obtained were adequate for all compounds, and the obtained values of R coefficients were for 0.9996, 0.9994, 0.9995, 0.9994 for (+)-catechin, (–)-epicatechin, ecysterone and rutin, respectively (Table 1).

Limits of detection (LOD) and limits of quantification (LOQ)

Limits of detection (LODs) and quantification (LOQs) were estimated from the standard deviation of the y-intercept (S_b) and the slope (a) of three calibration curves prepared in three low concentrations. The mathematical calculations were performed using the following equations: $LOD = 3.3S_b \cdot a^{-1}$ and $LOQ = 10S_b \cdot a^{-1}$, where a is the mean of slopes of the calibration curves and S_b is the SD of the y-intercept. For that, the same stock solution prepared for the determination of linearity was used. The three concentration levels for each compound were also prepared in MeOH/H₂O 1:1, ranging from (i) 0.2 to 1 $\mu\text{g mL}^{-1}$ for (+)-catechin, (ii) 0.3 to 1.5 $\mu\text{g mL}^{-1}$ for (–)-epicatechin, (iii) 1.6 to 7.8 $\mu\text{g mL}^{-1}$ for ecysterone, and (iv) 0.6 to 3 $\mu\text{g mL}^{-1}$ for rutin. All solutions also contained the internal standard sodium diclofenac at 15 $\mu\text{g mL}^{-1}$ and were injected in triplicate.

The results obtained for the LOD and LOQ for (+)-catechin, (–)-epicatechin, ecysterone and rutin were 0.06, 0.02, 0.07 and 0.03 $\mu\text{g mL}^{-1}$ and 0.18, 0.06, 0.22 and 0.11 $\mu\text{g mL}^{-1}$, respectively (Table 1).

Accuracy

Accuracy was determined by recovery studies, which was performed by standard addition of the analyte in the RSMS solution, in three different concentrations, considering the specified range of the analytical procedure. For that, previously analyzed standard and RSMS solutions were used to prepare three different concentration levels by spiking known amounts of the stock standards solution into the RSMS solution. Three replicates for each

level (low, intermediate and high, or at 66.7, 100.0 and 166.7 % levels, respectively) were prepared to obtain solutions containing 2.99, 8.99 and 14.99 $\mu\text{g mL}^{-1}$ of (+)-catechin, 4.18, 13.18 and 22.18 $\mu\text{g mL}^{-1}$ of (–)-epicatechin, 17.99, 64.55 and 111.11 $\mu\text{g mL}^{-1}$ of ecdysterone and 7.64, 25.64 and 43.64 $\mu\text{g mL}^{-1}$ of rutin. The percentage of recovery of each compound was analyzed using the validated method and the accuracy was calculated by the difference between the nominal and the experimentally measured contents.

Results show an average of recovery corresponded to 86.72% (low level), 88.71% (intermediate level) and 93.73% (high level), taking into account all compounds in each level. Considering each compound separately, the RSD was lower than 5% (Table 1).
