**Figure S1.** EDS and mapping analysis of CoNi$_2$-OH/$_L$-Asn. (a−d) EDS mapping of Co, Ni and Cl element, and (e) EDS of CoNi$_2$-OH/$_L$-Asn.

Figure S2. TGA analysis of CoNi$_2$-OH/$_L$-Asn

The TG curve of the CoNi$_2$-OH/$_L$-Asn sample in the temperature range of 25-800 °C (see figure below). The analysis of the TGA curve is based on a previous publication.[1] The CoNi$_2$-OH/$_L$-Asn underwent weight loss of 33.7% in four steps indicated by the zones I, II, III, and

IV on the graph. The weight loss below 50 °C (stage I) is ascribed to the removal of the adsorbed water. The weight loss (9.54%) between 50 and 145 °C (stage II) is assigned to the evaporation of the intercalated water molecules. The weight loss (20.36%) ranging from 145 to 400 °C (stage III) is associated with the loss of water molecules produced by dehydroxylation of the hydroxide layers combined with the partial loss of Cl^-. Finally, the stage IV ending at about 700 °C can be attributed to the loss of Cl^- ions. Therefore, the composition of the as-prepared CoNi$_2$-OH/L-Asn sample was estimated to be CoNi$_2$(OH)$_{4.05}$Cl$_{0.34}$·1.79H$_2$O (Co, 20.3%; Ni, 40.53%; OH$^-$, 23.77%; Cl$^-$, 4.19%; H$_2$O, 11.14%;). The predominant anionic species in the interlayer of the CoNi$_2$-OH/L-Asn sample was Cl$^-$ ions, which were accommodated in the interlayer together with water molecules.

**Figure S3.** SEM images of the Co$_x$Ni$_{2-x}$-OH/L-Asn at different Co: Ni feed ratio. (a) CoNi$_2$-OH/L-Asn, (b) CoNi-OH/L-Asn and (c) Co$_2$Ni-OH/L-Asn.

Figure S4. SEM images of the CoNi$_2$-OH at different LAs. (a-i) CoNi$_2$-OH/L-Glu, CoNi$_2$-OH/L-Asp, CoNi$_2$-OH/L-Asn, CoNi$_2$-OH/L-Phe, CoNi$_2$-OH/L-Met and CoNi$_2$-OH/L-Ser, CoNi$_2$-OH/L-Arg, CoNi$_2$-OH/L-Lys and CoNi$_2$-OH/L-His, respectively.

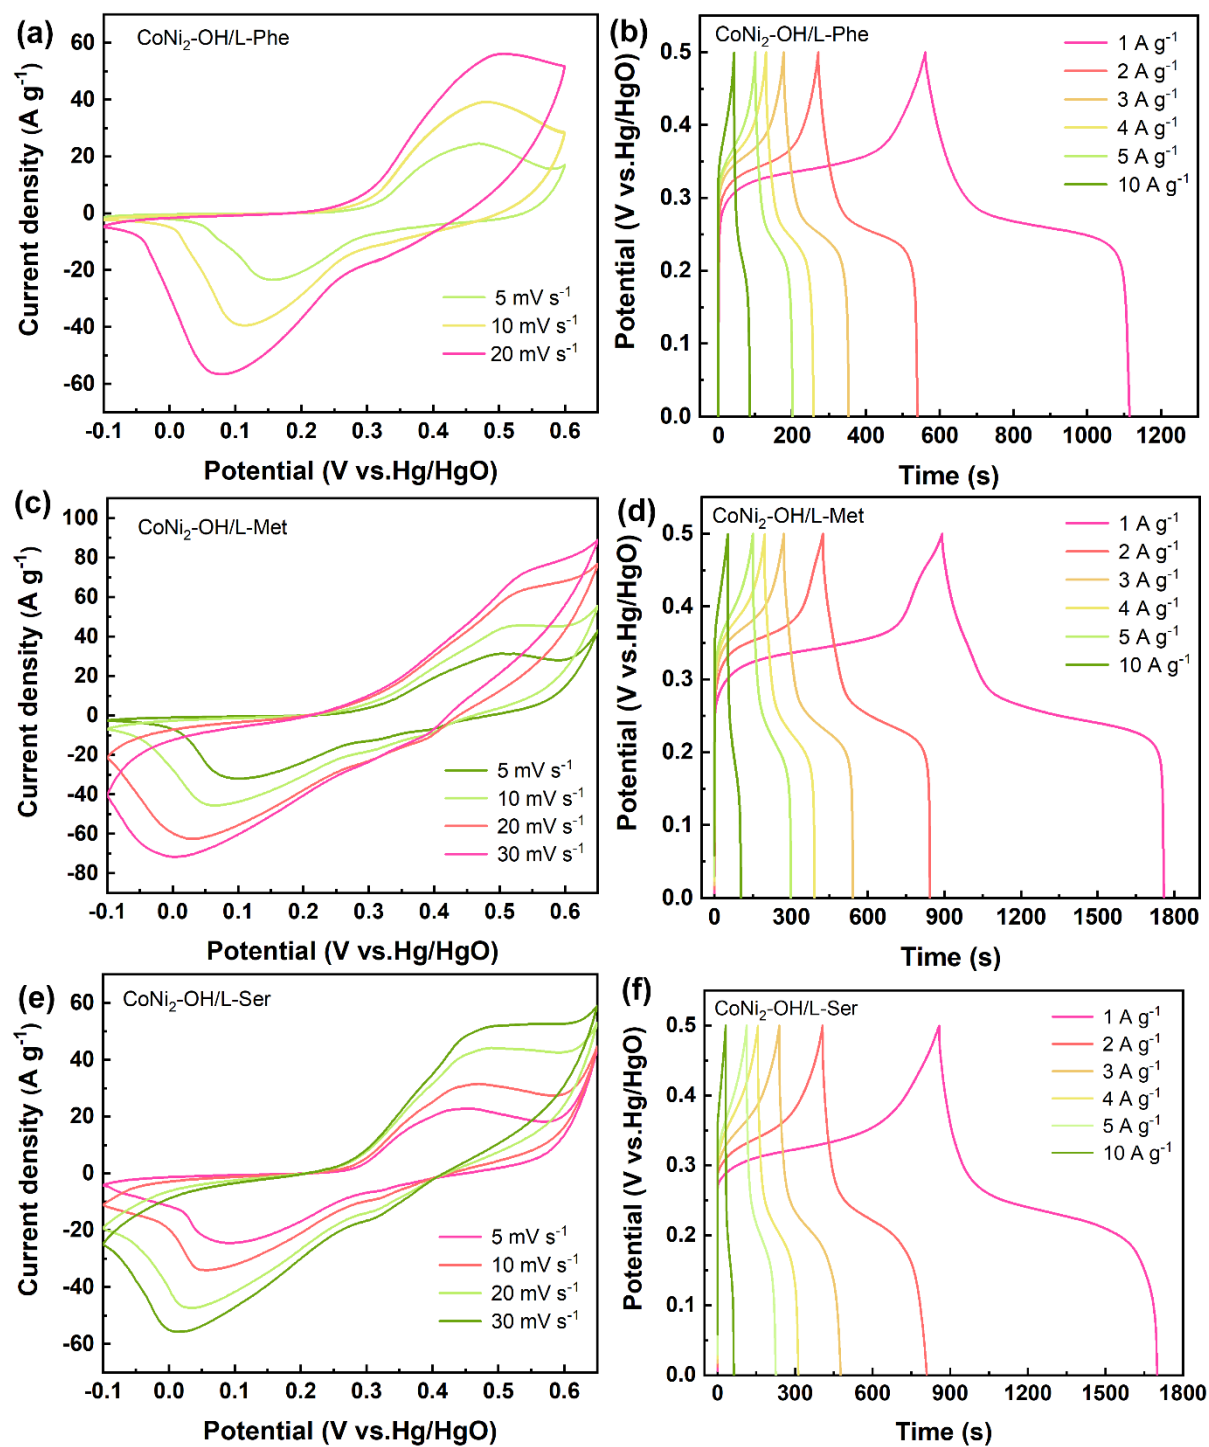

**Figure S13.** Cyclic voltammetry curves and galvanostatic discharge curves of CoNi$_2$-OH/L-Arg, CoNi$_2$-OH/L-His and CoNi$_2$-OH/L-Lys. (a, c, e) CV curves at different scan rates, respectively, and (b, d, f) GCD curves at different current densities.

Figure S14. Capacitive and diffusion-controlled contributions to charge storage. (a) CV curves of CoNi$_2$-OH/L-Asn at different scan rates. b) The plots of log(i) against log(v) for CoNi$_2$-OH/L-Asn. c) Separation of the capacitive and diffusion-controlled currents of CoNi$_2$-OH/L-Asn electrode at a scan rate of 5 mV s^{-1}. d) Relative contributions of the capacitive and diffusion-controlled charge storage processes at different scan rates.

Figure S15. Nyquist plots of Co$_x$Ni$_{2-x}$-OH/L-Asn electrodes.

We used electrochemical impedance spectroscopy (EIS) to evaluate the electrochemical performance

of the Co_xNi_{2-x}-OH/L-Asn electrodes (Fig. S15). The EIS cures show characteristic impedance semicircle of the transmission process in the high frequencies (HFs) zone and the characteristic straight line of the diffusion in the low-frequency zone. The Warburg impedance is caused by the polarization of the concentration difference. The inset image in Fig. S15 shows the equivalent circuit. The Nyquist plots obtained the intersection point of the semicircle of HFs on the real axis represents the series resistance (Rs) of the equivalent circuit, which mainly includes the intrinsic resistance and diffusion resistance of the active materials and the charge transfer resistance with the electrolyte. The diameter of the semicircle in the high-frequency region was ascribed to the charge-transfer resistance (Rct) linked to the exchanged current as defined in the Butler–Volmer equation. Real electrodes behave slightly more complex because of dispersion factors. These factors are mainly due to geometric aspects, such as electrode porosity and electrode roughness, especially for pseudocapacitors, active sites, and activation energy dispersion. Such fractal electrodes induce frequency dispersions of the electrical parameters. It is not accurate to simply consider the equivalent electrode interface dual-layer to a pure capacitor. To represent the electrical dispersions occurring in a real electrode, we used the constant phase element (CPE) introduced into the equivalent circuit. Fig. S15 demonstrates the estimation of Rs of $Co(OH)_2$/L-Asn, Co_2Ni-OH/L-Asn, CoNi-OH/L-Asn, $CoNi_2$-OH/L-Asn and $Ni(OH)_2$/L-Asn material as electrodes, and the values are 0.93, 0.66, 0.62, 0.59 and 0.45 Ω, respectively. The $CoNi_2$-OH/L-Asn has the lowest Rs than the other Co_xNi_{2-x}-OH/L-Asn electrodes, which can be attributed to the excellent structural properties.
