Experimental methods

Materials. All the starting materials were purchased from commercial suppliers and used without further purification. Copper(II) phthalocyanine (99%, CuPc), 4,5-dichlorophthalonitrile (99%), Cu(OAc)$_2$ (98%), K$_3$PO$_4$ (98%), Ni(NO$_3$)$_2$·6H$_2$O (≥97.0%), NiCl$_2$·6H$_2$O (≥98%), Cu(NO$_3$)$_2$·3H$_2$O (99-104%), Na$_2$SO$_4$ (≥99.0%), and gelatin (tested according to Ph Eur) were purchased from Sigma-Aldrich Chemie GmbH. H$_2$SO$_4$ (≥95%), H$_2$O$_2$ (>30% w/v), and n-pentanol (99%) were provided by Fisher Scientific GmbH. 1,2,4,5-benzenetetramine tetrahydrochloride (97%), enzophenone imine (98%), *o*-phenylenediamine (99%), tris(dibenzylideneacetone) dipalladium(0) (99%), and racemic-2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl (97%) were supplied by Fluorochem Limited. Ammonia solution (50% v/v) and 1,8-Diazabicyclo[5.4.0]undec-7-ene (99%) were obtained from abcr GmbH. The carbon cloth without a microporous layer (W0S1009, areal density: 12 mg cm^{-2}) was purchased from Fuel Cell Store, USA.

Pretreatment of carbon cloth. Carbon cloths were pretreated with piranha solution (H$_2$SO$_4$: H$_2$O$_2$ = 7 : 3) at 60 °C overnight. Afterwards, they were washed with deionized water and acetone. Finally, the hydrophilic substrates were dried under vacuum overnight for further use.

In-situ growth of M$_2$[CuPc(NH)$_8$] (M = Ni or Cu) on carbon cloth. Copper (II) 2,3,9,10,16,17,23,24-octaaminophthalocyanine octahydrochloride (OAPcCu, CuPc(NH$_2$)$_8$·8HCl) was synthesized according to our previous report.[1] CuPc(NH$_2$)$_8$·8HCl (5 mg) was dissolved in dimethyl sulfoxide (DMSO, 3 mL) and ammonia solution (50% v/v, 0.1 mL) in a 10 mL vial. Ni(NO$_3$)$_2$·6H$_2$O (3 mg) in DMSO (1 mL) and ammonia solution (50% v/v, 0.1 mL) was added to the mixture in a sand bath at 60 °C under air. The reaction mixture was stirred for 10 min before it was transferred to a 10 mL vial with a piece of pretreated carbon cloth (1 cm × 3 cm, immersed part: 1 cm × 2 cm). After 8 h, the reaction mixture was cooled down to room temperature, and then the carbon cloth was taken out, washed with DMSO, H$_2$O, and acetone, respectively. Finally, it was dried under vacuum overnight, obtaining the

additive/binder-free electrode. The mass of $Ni_2[CuPc(NH)_8]$ grown on carbon cloth was measured by calculating the weight increase of the substrate after the *in-situ* growth with a microbalance (OHAUS Explorer® Analytical, the accuracy is 0.01 mg). The mass loading can be controlled from 0.5 to 2.0 mg cm^{-2} by repeated growth. If no otherwise specified, the areal loading mass of all the samples is about 1.1 mg cm^{-2}.

For the synthesis of $Cu_2[CuPc(NH)_8]$, $CuPc(NH_2)_8 \cdot 8HCl$ (5 mg) was dissolved in DMSO (3 mL) and ammonia solution (50% v/v, 0.1 mL) in a 10 mL vial with a piece of pretreated carbon cloth (1 cm × 3 cm, immersed part: 1 cm × 2 cm). $Cu(NO_3)_2 \cdot 3H_2O$ (2.5 mg) in DMSO (1 mL) and ammonia solution (50% v/v, 0.1 mL) was added to this mixture in a sand bath at 30 °C under air. The reaction mixture was stirred for 3 min and kept at this temperature for 8 h. The mass of $Cu_2[CuPc(NH)_8]$ grown on carbon cloth was measured by calculating the weight increase of the substrate after the *in-situ* growth with a microbalance (OHAUS Explorer® Analytical, the accuracy is 0.01 mg). The mass loading can be controlled from 0.5 to 2.0 mg cm^{-2} by repeated growth. If no otherwise specified, the areal loading mass of all the samples is about 1.1 mg cm^{-2}. The $M_2[CuPc(NH)_8]$ (M = Ni or Cu) powder samples were obtained without adding the carbon cloth by the same procedure.

Preparation of Ni(BTI) (BTI = 1,2,4,5-benzenetetraimine) coordination polymer on carbon cloth. A solution of $Ni(NO_3)_2 \cdot 6H_2O$ (11.9 mg) in water (2 mL) and ammonia solution (50% v/v, 0.3 mL) was added to a solution of 1,2,4,5-benzenetetramine tetrahydrochloride (14.2 mg) in water (7 mL) in a 15 mL vial with a piece of pretreated carbon cloth (1 cm × 3 cm, immersed part: 1 cm × 2 cm) at 60 °C in a sand bath. This mixture was stirred for 3 min and then kept for 2h. The obtained Ni(BTI) coordination polymer grown carbon cloth was washed for several times with deionized water and acetone, and finally dried under vacuum overnight. The areal loading mass is about 1.5 mg cm^{-2}.

Preparation of the CuPc electrode. The CuPc electrode was prepared by mixing commercial CuPc powder, acetylene black, and polytetrafluoroethylene (PTFE) in a weight ratio of 4:5:1

with the help of ethanol. The mixture was pressed into a film, and then dried at 80 °C overnight in a vacuum oven. After drying, the film was cut into many disks, which were subsequently pressed onto carbon cloths to act as the working electrodes. The areal loading mass is 1-2 mg cm^{-2}.

Preparation of the thick $M_2[CuPc(NH)_8]$ (M = Ni or Cu) free-standing electrodes. The thick $M_2[CuPc(NH)_8]$ free-standing electrodes were prepared by mixing $M_2[CuPc(NH)_8]$ powders, acetylene black, and PTFE in a weight ratio of 7:2:1 with the help of ethanol. The mixture was pressed into a film, and then dried at 80 °C overnight in a vacuum oven. After drying, the film was cut into many disks with diameters of 8 mm. The areal loading mass is 10 mg cm^{-2}. The electrochemical measurements of the thick $M_2[CuPc(NH)_8]$ electrodes were performed in the three-electrode Swagelok cell with the $M_2[CuPc(NH)_8]$ disc as the working electrode, over-capacitive activated carbon as the counter electrode, a glass fiber separator (Whatman, GF/D) saturated with 1 M Na_2SO_4, and an Ag/AgCl (3 M KCl) reference electrode.

Fabrication of quasi-solid-state symmetric SCs. To fabricate quasi-solid-state symmetric SCs, two $Ni_2[CuPc(NH)_8]$ electrodes were sandwiched together with a separator and gelatin/Na_2SO_4 gel electrolyte. The weight balance of the symmetric device was carried out based on equation ($C_+ \times \Delta E_+ \times m_+ = C_- \times \Delta E_- \times m_-$), where C is the specific capacitance in the three-electrode test, ΔE is the voltage range, and m is the mass of the active material. Based on the specific capacitances calculated from Figure S25, the mass ratio of the two $Ni_2[CuPc(NH)_8]$ electrodes (m_+/m_-) is determined to be 1.4. The gelatin/Na_2SO_4 gel electrolyte was prepared by mixing gelatin powder (2 g) and Na_2SO_4 (2.84 g) in 20 mL deionized water at 65°C for 5 h with vigorously stirring until totally dissolved.

Density functional theory (DFT) calculations. A density functional mapping of $Ni_2[CuPc(NH)_8]$ was carried out with the DFT method using Gaussian16 software package.[2] Structure of $Ni_2[CuPc(NH)_8]$ were optimized with Becke's three-parameter hybrid exchange

functional and the Lee–Yang–Parr correlation functional (B3LYP) and the 6-311G (d,p) basis set. Surface charge mapping was visualized with GaussView 6.0 software.

Materials characterization. Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) images were obtained with a field emission scanning electron microscope (FESEM, Zeiss Gemini 500) and a high-resolution transmission electron microscope (HRTEM, JEM-2100, JEOL, Japan), respectively. Raman analysis was performed by using a Raman microscope (LabRAM (HR 800), HORIBA JOBIN-Yvon) with a 532 nm Nd:YAG laser and a liquid-nitrogen cooled charge coupled device camera. The X-ray photoelectron spectroscopy (XPS) spectra were acquired using a Kratos Axis UltraDLD spectrometer (Kratos Analytical- A Shimadzu Group Company) with a monochromatic Al-Kα source (1486.6 eV). X-ray diffraction (XRD) patterns were obtained on an X-ray diffractometer (Dectris Mythen 1K Strip Detector, Stoe Stadi-P) using Cu-Kα radiation (λ = 0.154 nm) at 40 kV and 30 mA at room temperature. Electron paramagnetic resonance (EPR) spectra were collected on a Bruker BioSpin Gmbh spectrometer equipped with a standard mode cavity. Nitrogen adsorption isotherms were measured at 77.3 K with a Quantachrome SI-MP Instrument Automated Surface Area and Pore Size Analyzer.

Electrochemical measurement. Cyclic voltammetry (CV), galvanostatic charge/discharge (GCD) measurements, and electrochemical impedance spectroscopy (EIS) were employed with a CHI 660E electrochemical workstation. The electrochemical study of individual electrodes (1 cm × 2 cm) was performed in a three-electrode system with a Pt wire counter electrode and an Ag/AgCl (3 M KCl) reference electrode. For the linear sweep voltammetry (LSV) test of the aqueous electrolyte, two Pt foils and Ag/AgCl (3 M KCl) were employed as working, counter, and reference electrodes, respectively.

Calculations. The specific capacitance (C, F g^{-1}) based on the CV curves were calculated according to the following equation (1), where m is the mass of active material (g), v is the scan

rate (V s^{-1}), V_f and V_i are the integration potential limits of CV curves, $I(V)$ is the voltammetric current (in amperes), and $\int_{V_i}^{V_f} I(V)\,dV$ is the integrated area from CV curves.

$$C = \frac{1}{2 \times m \times v \times (V_f - V_i)} \int_{V_i}^{V_f} I(V)\,dV \tag{1}$$

The specific capacitance (C, F g^{-1}) was also calculated from the GCD curves according to the following equation (2), where I/m is the current density (A g^{-1}), t is the discharge time (s), and v is the voltage range (V).

$$C_A = \frac{I}{m} \times \frac{t}{v} \tag{2}$$

The areal energy densities (E, Wh kg^{-1}) and power densities (P, W kg^{-1}) were calculated from equations (3) and (4), where $\triangle V$ is the discharge voltage range (V) and $\triangle t$ is discharge time (s).

$$E = \frac{1}{2} \times C \times \frac{(\Delta V)^2}{3{,}600} \tag{3}$$

$$P = \frac{E}{\Delta t} \times 3600 \tag{4}$$

Figure S3. XRD pattern of the pristine carbon cloth.
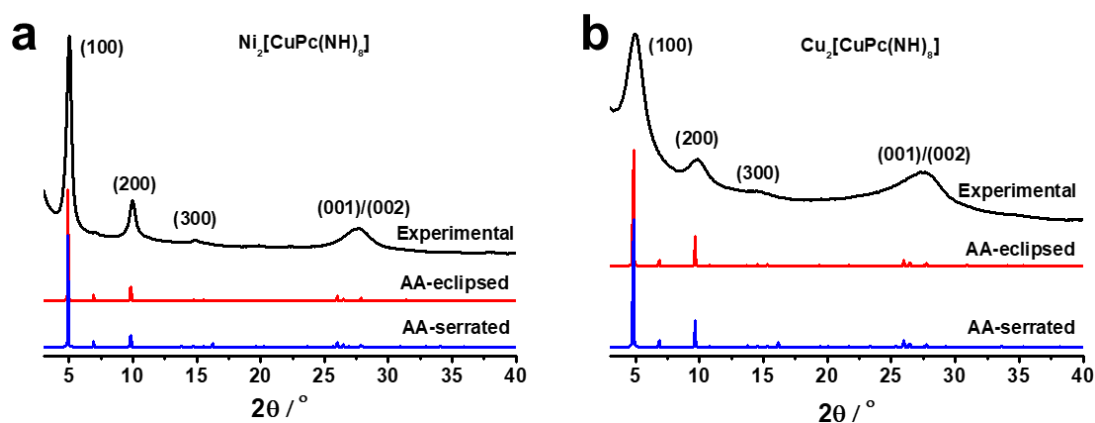

**Figure S4.** Experimental and simulated XRD patterns of (a) $Ni_2[CuPc(NH)_8]$ and (b) $Cu_2[CuPc(NH)_8]$.

Earlier studies verified the four-coordination geometries of the metal-bis(iminobenzosemiquinoid) model compounds ($M[C_6H_4(NH)_2]_2$, M = Ni or Cu), which serve as the linkage in our $M_2[CuPc(NH)_8]$ 2D *c*-MOF, *e.g.*, nickel-bis(iminobenzosemiquinoid) (*J. Am. Chem. Soc.* **1966**, *88*, 5201) and copper-bis(iminobenzosemiquinoid) (*Polyhedron* **1991**, *10*, 955). Moreover, in the previously reported M-NH-linked (M = Ni or Cu) 2D *c*-MOFs (based on benzene/triphenylene, *e.g.*, *J. Am. Chem. Soc.* **2014**, *136*, 8859; *Nat. Energy* **2018**, *3*, 30; *Angew. Chem. Int. Ed.* **2015**, *54*, 4349; *J. Am. Chem. Soc.* **2017**, *139*, 13608), both the Ni-NH and Cu-NH linkages were confirmed to possess a four-coordination geometry by identifying the consistency of experimental as well as calculated XRD patterns and comparing the peak positions in the experimental XRD patterns for Ni-NH- and Cu-NH-linked MOFs. Based on the literature information, the DFT calculation was employed in our study to simulate the structures of $M_2[CuPc(NH)_8]$ with the four-coordination geometry. We found that our experimental XRD results (Figure 1b) agree well with the simulated results (Figure S4-S6). Thereby, we conclude that both $Ni_2[CuPc(NH)_8]$ and $Cu_2[CuPc(NH)_8]$ are indeed equipped with four-coordination M-NH-linkage.
Figure S5. Top and side views of simulated (a) AA-eclipsed and (b) AA-serrated stacked bilayer of $Ni_2[CuPc(NH)_8]$ (C: grey, N: blue, Cu: orange, Ni: purple, H: white). $Ni_2[CuPc(NH)_8]$ can be defined by square unit cells with a=b=18.0 Å. The Ni-Ni distances are calculated as 12.73 and 18.00 Å in the 2D plane.
Figure S6. Top and side views of simulated (a) AA-eclipsed and (b) AA-serrated stacked bilayer of $Cu_2[CuPc(NH)_8]$ (C: grey, N: blue, Cu: orange, H: white). $Cu_2[CuPc(NH)_8]$ can be defined by square unit cells with a=b=18.30 Å. The Cu-Cu distances are calculated as 9.15, 12.94, and 18.30 Å in the 2D plane.

Figure S12. EPR spectrum of $Ni_2[CuPc(NH)_8]$ recorded at 3 K. EPR spectroscopy of $Ni_2[CuPc(NH)_8]$ presents a main peak with a *g*-factor of 2.05 and a shoulder with a *g*-factor of 2.14, which correspond to the Cu^{II} atoms in the CuPc unit. Furthermore, the EPR spectrum of $Ni_2[CuPc(NH)_8]$ displays no signals for organic radicals. The XPS spectra reveal the absence of charge-balancing counter ions and suggest a charge-neutral framework. Based on the XPS and EPR results, we propose a reasonable radical structure in Figure 1a, which remains conjugated and contains delocalized diradical in the CuPc unit.

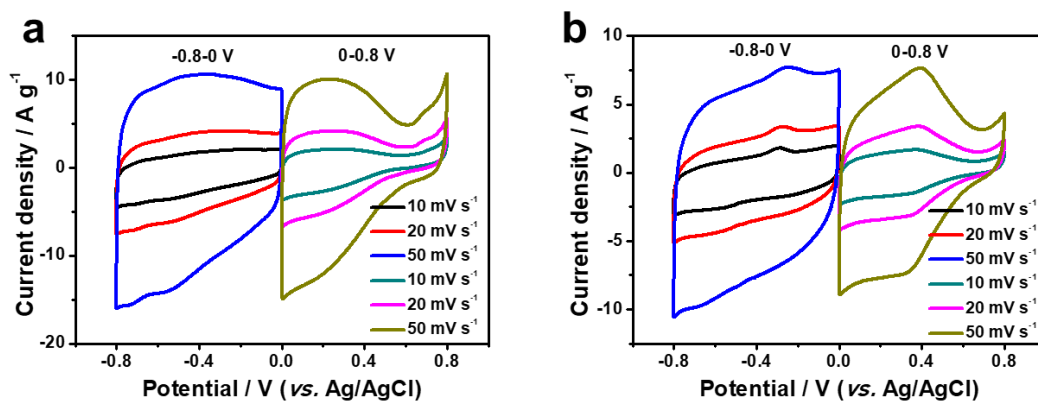

Figure S25. CV curves on both sides of open-circuit potentials (OCPs) at 10, 20, and 50 mV s^{-1} of (a) the $Ni_2[CuPc(NH)_8]$ electrode and (b) the $Cu_2[CuPc(NH)_8]$ electrode. The OCPs of $Ni_2[CuPc(NH)_8]$ and $Cu_2[CuPc(NH)_8]$ were measured to be 0.01 and −0.02 V, respectively. According to the CV curves, the specific capacitances of $Ni_2[CuPc(NH)_8]$ are 191.7 F g^{-1} (−0.8-0 V) and 141.2 F g^{-1} (0-0.8 V) at 10 mV s^{-1}, respectively. Meanwhile, the specific capacitances of $Cu_2[CuPc(NH)_8]$ are calculated to be 154.6 F g^{-1} (−0.8-0 V) and 111.4 F g^{-1} (0-0.8 V) at 10 mV s^{-1}, respectively. According to these calculated specific capacitances, we assembled the two-electrode quasi-solid-state supercapacitors based on the $Ni_2[CuPc(NH)_8]$ electrodes.
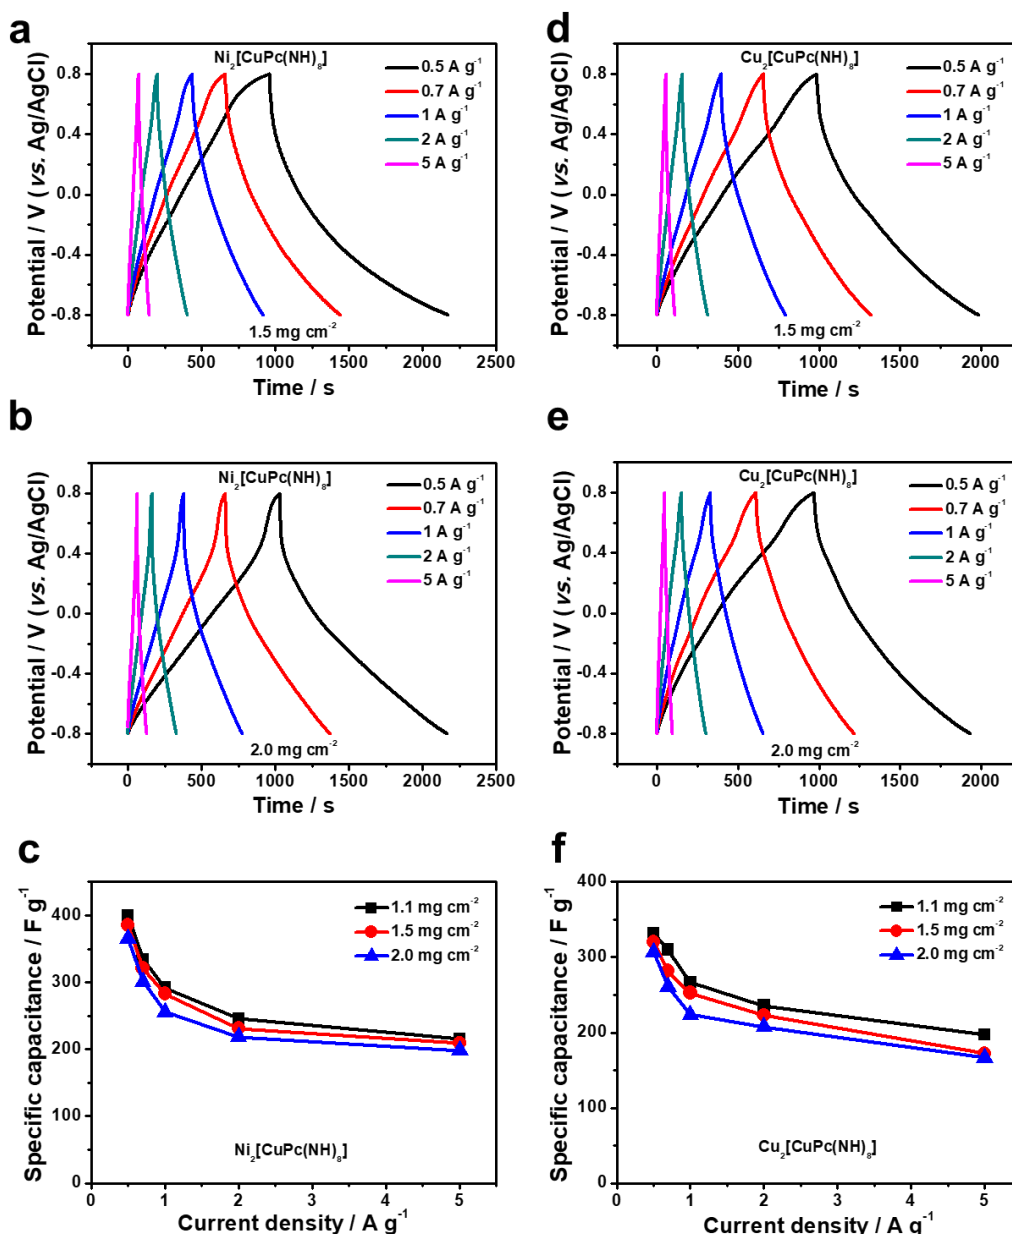

Figure S26. Specific capacitances of (a-c) the Ni₂[CuPc(NH)₈] electrodes and (d-f) the Cu₂[CuPc(NH)₈] electrodes with different mass loadings as a function of current densities. The maximum specific capacitances of Ni₂[CuPc(NH)₈] electrodes with the mass loading of 1.1, 1.5, and 2.0 mg cm⁻² are 399.7, 385.6, and 365.3 F g⁻¹, respectively. The maximum specific capacitances of Cu₂[CuPc(NH)₈] electrodes with the mass loading of 1.1, 1.5, and 2.0 mg cm⁻² are 331.9, 320.2, and 306.9 F g⁻¹, respectively.

Figure S35. N *1s* XPS spectra of the Ni₂[CuPc(NH)₈] electrode at different charge/discharge potentials.

As shown in Figure 3d and Figure S35a, negligible change in the N *1s* signal was detected for Ni₂[CuPc(NH)₈] at potential of −0.8 V (@A and I in Figure S35a), −0.4 V (@B and H in Figure S35a), and 0 V (@C and G in Figure S35a). The N *1s* spectrum of Ni₂[CuPc(NH)₈]@A can be deconvoluted into three peaks at 400.4, 399.4, and 398.5 eV, corresponding to three types of N (N-Cu, N=C-N, and N-Ni, respectively) in the framework (Figure S35b). However, after the oxidation reaction of the phthalocyanine building block (0.8 V, @E), the N *1s* signal shifted by about +0.3 eV (Figure 3d and S35c). Deconvolution of the spectrum indicates the presence of an additional type of N, which is ascribed to the formation of π-cation radical in the phthalocyanine moiety.
