## <sup>2</sup> Kinetic Model

- <sup>3</sup> The Oregonator model can be derived from the FKN mechanism<sup>1</sup> by considering the following set
- <sup>4</sup> of kinetic steps:<sup>2</sup>

$HBrO_2 + H^+ + Br^-$	$\xrightarrow{k_1}$	2HBrO	$k_1 = 2 \times 10^6 \text{ s}^{-1} \text{ M}^{-2}$
$\mathrm{BrO}_3^- + 2\mathrm{H}^+ + \mathrm{Br}^-$	$\xrightarrow{k_2}$	$HBrO + HBrO_2$	$k_2 = 2 \text{ s}^{-1} \text{ M}^{-3}$
2HBrO <sub>2</sub>	$\xrightarrow{k_3}$	$\rm HBrO + BrO_3^- + \rm H^+$	$k_3 = 3000 \text{ s}^{-1} \text{ M}^{-1}$
$HBrO_2 + BrO_3^- + H^+$	$\frac{\frac{k_4}{k_{-4}}}{k_{-4}}$	2BrO <sub>2</sub>	$k_4 = 42 \text{ s}^{-1} \text{ M}^{-2},$
			$k_{-4} = 2 \times 10^8 \text{ s}^{-1} \text{ M}^{-1}$
$BrO_2^{\cdot} + Fe(II)$	$\xrightarrow{k_5}$	$HBrO_2 + Fe(III)$	$k_5 = 5 \times 10^6 \text{ s}^{-1} \text{ M}^{-1}$
organic substrate + Fe(III)	$\xrightarrow{k_6}$	$Br^- + Fe(II)$ + organic prod.	$k_6 = 0.17 \text{ s}^{-1} \text{ M}^{-2}$

6

5

<sup>7</sup> The first five steps describe the "oxidation phase" (OP) while the last step simplifies "resetting <sup>8</sup> of the chemical clock". If, following the traditional notation, we set  $H = [H^+]$ ,  $A = [BrO_3^-]$ , <sup>9</sup> B = organic substrate,  $X = [HBrO_2]$ ,  $Y = [Br^-]$ , Z = [Fe(III)], P = [HBrO],  $W = [BrO_2^-]$  and <sup>10</sup> C = [Fe(II)], the corresponding kinetic equations read

$$\frac{dX}{dt} = -k_1 HXY + k_2 AH^2 Y - 2k_3 X^2 - k_4 AHX + k_{-4} W^2 + k_5 WC$$
(1)

$$\frac{\mathrm{d}Y}{\mathrm{d}t} = -k_1 HXY - k_2 A H^2 Y + k_6 B Z \tag{2}$$

$$\frac{\mathrm{d}Z}{\mathrm{d}t} = k_5 W C - k_6 B Z \tag{3}$$

$$\frac{dW}{dt} = 2k_4 A H X - 2k_{-4} W^2 - k_5 W C$$
(4)

$$\frac{\mathrm{d}C}{\mathrm{d}t} = -k_5 W C + k_6 B Z. \tag{5}$$

Applying the steady-state approximation, dW/dt = 0,<sup>3</sup> allows us to eliminate eq. (4) and substitute the term  $k_5WC$  with  $2k_4AHX$  (since  $k_5CW = 2k_4AHX - 2k_{-4}W^2$  and  $k_5C >> 2k_{-4}W$  at almost all the times during the reaction). The autocatalytic term also needs to be modified in order to ensure the conservation of the global amount of the catalyst and to avoid an unlimited depletion of its reduced form which may cause divergent solutions to the kinetic equations. A typical correction to this term is  $k_4AHXC/(C + c_{min})$  (see<sup>3</sup> and references therein), where  $c_{min}$  is a small constant. By replacing  $C = C_0 - Z$  (where  $C_0$  is the initial concentration of the catalyst), the previous correction takes the form  $k_4AHX(C_0 - Z)/(C_0 - Z + c_{min})$ .

19

20 The final kinetic model is

$$\frac{\mathrm{d}X}{\mathrm{d}t} = -k_1 HXY + k_2 A H^2 Y - 2k_3 X^2 + k_4 A HX (C_0 - Z) / (C_0 - Z + c_{min})$$
(6)

$$\frac{\mathrm{d}Y}{\mathrm{d}t} = -k_1 HXY - k_2 A H^2 Y + k_6 B Z \tag{7}$$

$$\frac{dZ}{dt} = 2k_4 AHX(C_0 - Z)/(C_0 - Z + c_{min}) - k_6 BZ.$$
(8)

Starting from this system, we can reduce the global process to OP by neglecting the term  $k_6BZ$ . The dimensionless form of the OP kinetic equations is written by introducing the following time and concentrations scales { $t_0 = 1/(k_2A_0H_0^2)$ ,  $X_0 = k_4A_0H_0/2k_3$ ,  $Y_0 = k_4A_0/k_1$ ,  $Z_0 = k_4^2A_0/(k_2k_3)$ }:

$$\frac{\mathrm{d}x}{\mathrm{d}\tau} = \frac{1}{\varepsilon_1} (-hxy + qah^2y - x^2 + (1 - z/z_m)/(1 - z/z_m + \varepsilon)ahx)$$
(9)

$$\frac{\mathrm{d}y}{\mathrm{d}\tau} = -\frac{1}{q}hxy - ah^2y \tag{10}$$

$$\frac{\mathrm{d}z}{\mathrm{d}\tau} = (1 - z/z_m)/(1 - z/z_m + \varepsilon)ahx \tag{11}$$

where  $q = 2k_2k_3/(k_1k_4)$ ,  $\varepsilon_1 = k_2H_0/k_4$ ,  $\varepsilon = c_{min}/C_0$ ,  $z_m = Z_0/C_0$  and  $A_0, H_0$  are the dimensional initial concentration of the bromate and the sulfuric acid, respectively, and define the concentration scales for *A* and *H*.

27

The dimensionless model to describe the bulk behavior of the full BZ system including the resetting step is obtained by using the initial concentration of the organic substrate  $B_0$  to define the time scale  $t_0 = 1/(k_6B_0)$  and the following concentration scales for the chemical species { $X_0 = k_4A_0H_0/2k_3$ ,  $Y_0 = k_4A_0/k_1$ ,  $Z_0 = (k_4A_0H_0)^2/k_3k_6B_0$ }

$$\frac{\mathrm{d}x}{\mathrm{d}\tau} = \frac{1}{\varepsilon_1} (-hxy + qah^2y - x^2 + (1 - z/z_m)/(1 - z/z_m + \varepsilon)ahx)$$
(12)

$$\frac{\mathrm{d}y}{\mathrm{d}\tau} = \frac{1}{\varepsilon_2}(-hxy - qah^2y + bz) \tag{13}$$

$$\frac{\mathrm{d}z}{\mathrm{d}\tau} = (1-z/z_m)/(1-z/z_m+\varepsilon)ahx-bz. \tag{14}$$

Note that the full BZ model presents a different definition of the parameter  $\varepsilon_1$  with respect to 32 the OP kinetics and also includes  $\varepsilon_2$ . In both models the parameter q is the same ratio of kinetic 33 constants independent of chemical concentrations. Varying the value of q allows one to tune the 34 shape, the amplitude and the frequency of the chemical oscillations by affecting the topology of the 35 related limit cycle in the phase portrait. The best room-temperature estimate for parameters q from 36 the rate constants of the FKN model is around 0.00015 (uncertainty of perhaps 50%). However, 37 in the literature<sup>4,5</sup> this parameter is typically ranged between 0.0001 and 0.01. Parameter q can 38 also control the transition from the oscillatory to the excitable regime as can be observed in Fig.1, 39 where the oscillation period is characterized as a function of  $B_0$  for q = 0.0001 and 0.01. 40

The increment of q, at  $B_0$  fixed, produces a decrease of the oscillation period. A decrease of the oscillation period is also registered by decreasing  $B_0$  with q fixed. Note that when q = 0.01 the system switches from the oscillatory to the excitable regime if  $B_0 \le 0.3$  M.

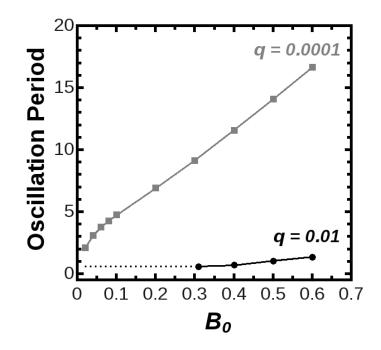

Figure 1: Dependence of the bulk oscillation period upon q and  $B_0$ . The dotted line represents the domain of  $B_0$  where the system is excitable when q = 0.01.
