Supporting Information for

Measurement of Gas and Aerosol Phase Absorption Spectra across the Visible and Near-IR

using Supercontinuum Photoacoustic Spectroscopy

■ SUPPORTING INFORMATION

The Supporting Information contains further details related to the characterization of the supercontinuum laser for photoacoustic measurements such as the beam diameter and output power density as a function of wavelength and a table containing the specific wavelengths and bandwidths used and the corresponding limits of detection. The integrated absorption coefficients of water vapor for each wavelength at 10 % RH and STP is also included. We provide plots of the absorption spectra calculated using the High Resolution Transmission 2012 (HITRAN 2012) database and the overlap of the corresponding output of the tunable wavelength and bandwidth filter. The measured and calculated absorption coefficients as a function of RH at $\lambda = 725$ nm and 820 nm is included to demonstrate the linear response of our microphone to RH. Finally, significant discussion on the determination of nigrosin's wavelength dependent refractive index is included.

Tunable wavelength and bandwidth filter output beam diameter. The $1/e^2$ beam diameter of the tunable wavelength and bandwidth filter was measured as a function of wavelength and bandwidth and is shown in Fig. S2. The beam diameter was measured using a scanning knife-

22   edge beam profiler (ThorLabs Omega Meter WM100).[1] The beam width of a laser beam with a

23   Gaussian profile is

24   $D_{\text{beam}} = 4\pi f T_{\text{r}} * 16002$ μm   (S1)

25   where f is the rotation speed of the profiler drum (10 Hz) and T_{r} is the rise time from 16 % to 84

26   % total power. As the output of the tunable wavelength filter with variable bandwidth is not

27   Gaussian, the measured beam diameter was corrected using

28   $D_{\text{Corr}} = \frac{D_{\text{beam}}}{M_{\text{k}}}[0.81(M_{\text{k}} - 1) + 1]$ (S2)

29   where M_{k} is square root of the times-diffraction-limit factor ($M^2 = 1.1$). In order to not overload

30   the profiler sensor, the output of the tunable wavelength filter with variable bandwidth was

31   passed through an O.D. 3 neutral density filter prior to measurement.

32

33   **Figure S1:** Output $1/e^2$ beam diameter of the tunable wavelength and bandwidth filter output as

34   a function of wavelength for the bandwidths used presently.

35   **Tunable wavelength and bandwidth filter output power density.** The power distribution of

36   the tunable wavelength and bandwidth filter was measured for each center wavelength longer

37   than 600 nm using an optical spectrum analyzer (Yokogawa AQ6370C). The total power was

38   measured at the center wavelength using a calibrated power meter. Results are shown in Fig. S2
39   and Table S1.

40

41 **Figure S2:** Output power density of the output of the tunable wavelength filter with variable

42 bandwidth.

43 **Table S1:** Bandwidth, average peak-to-peak power, the 5 min. limit of detection and water

44 vapor absorption coefficient at 10 % RH for each center wavelength used in the collection of

45 aerosol absorption spectra.

Wavelength (nm)	Bandwidth (nm)	Laser Power ($\times 10^{-2}$ W)	LOD ($\times 10^{-5}$ m^{-1})	α_{abs} H$_2$O$_{(g)}$ ($\times 10^{-6}$ m^{-1}, 10% RH)*

47   **Calculated water vapor absorption spectra.**   The absorption spectra of water vapor was

48   calculated using HITRAN2012 at each wavelength used and are shown in Fig. S-3 through S-22.

49   The corresponding laser power distributions are shown for wavelengths longer than 625 nm (the

50   optical spectrum analyzer used presently only detects wavelengths longer than 600 nm).

51   Atmospheric conditions at STP with a 10 % relative humidity were used.   All plots have the

52   same y-axis scale.

**Microphone responsivity.** The response of the microphone to water vapor was measured at

the peak absorption wavelengths of 725 nm and 820 nm and is shown in Fig. S23. The humidity

was measured in the increasing direction on one day and then both increasing and decreasing

directions on another day. Figure shows the average of those 3 scans. Error bars are 2σ. RH

was allowed to stabilize for 5 min before the absorption was measured. The relative responses

are 1.04 ± 0.04 and 0.97 ± 0.04 at 725 and 820 nm, respectively.

121

122 **Figure S23:** Microphone response as a function of RH at the peak absorption wavelengths of

123 725 nm and 820 nm. Grey line corresponds to 1 to 1.

124 **Determination of Nigrosin Refractive Index.** The refractive index of nigrosin aerosol at $\lambda =$

125 405 nm and 660 nm was determined by measuring the number concentration and extinction mass

126 distributions at multiple particle diameters, calculating the corresponding extinction cross

127 sections and fitting these cross sections with Mie theory. The block diagram for this experiment

128 can be seen in Fig. S24.

129

130 **Figure S24:** Block diagram of the experimental setup to determine the refractive index of

131 nigrosin.

132 The use of a tandem DMA, aerosol particle mass analyzer (APM), cavity ring-down

133 spectrometer (CRD) and CPC for the isolation of a single particle charge of interest was first

134 demonstrated in Radney et al. (2014).[2] Briefly, aerosols are selected by electrical mobility by a

135 DMA. The voltage of the APM (Kanomax 3601) is ramped at a constant rotation speed to

136 generate a distribution of particle masses at a given electrical mobility. The number

137 concentration and extinction are continuously measured by a CPC and CRD, respectively, during

138 the scan. From the measured distributions, C_{ext} as a function of mass is calculated in order to

139 isolate the particle distribution of interest (charge of + 1) from others present (i.e. those

140 possessing equivalent electrical mobility and charge > 1) via the slope of C_{ext} as in Radney et at

141 (2014)[2]; see the Supporting Information for a description of the calculation. The number

142 concentration distributions are fit using a number of Gaussian distribution functions

143 corresponding to the number of charges present

144   $N = \sum A_{N,q} * \exp\left(\frac{-(m - m_{p,q})^2}{2\sigma_{N,q}^2}\right)$ (S3)

145   where A_N is the peak amplitude, m_p is the average mass and σ_N is the $e^{-1/2}$ half width of the

146   distribution. An identical equation can be derived for extinction by replacing N with α_{ext}. The

147   subscript q denotes the number of charges on the particle. From the Gaussian fits of the

148   distributions of concentration and extinction versus mass (Eq. 5 in manuscript), the effective

149   density (ρ_{eff}) is calculated as

150   $\rho_{eff} = \frac{6m_{p,1}}{\pi D_m^3}$ (S4)

151   where D_m is the mobility diameter set by the DMA. The average extinction cross section is

152   $C_{ext} = \int \frac{\alpha_{ext}}{N} = \frac{A_{\alpha_{ext}}\sigma_{\alpha_{ext}}}{A_N \sigma_N}$ (S5)

153   The calculated C_{ext} are within 3 % to values calculated using Mie theory when using ammonium

154   sulfate aerosol.[3] The refractive index is then calculated by minimizing the merit function χ^2

155   where[4]

156   $\chi^2(m,k) = \sum_{i=1}^{N}\left[\frac{\left(C_{ext,measured} - C_{ext,calculated}(m,k)\right)_i^2}{\sigma_{ext,i}^2}\right]$ (S6)

157   Here, $\sigma_{ext,i}$ represents the $k = 2$ uncertainty in C_{ext} at a given mobility diameter and mass

158   combination i. From these calculations, the uncertainty ($k = 2$) in our refractive index was

159   approximated from the locus of values satisfying

160   $\chi^2 - \chi_{min}^2 \leq \chi_{crit}^2$ (S7)

161   at a 95% confidence interval for the given degrees of freedom where χ_{crit}^2 represents the upper-

162   tail critical value. Particles spanning 100 nm $\leq D_m \leq$ 450 nm were measured at 50 nm intervals

163   for λ = 405 nm and 150 nm $\leq D_m \leq$ 325 nm were measured at 25 nm intervals for λ = 660 nm.

164   Extinction cross sections were calculated using a homogeneous sphere Mie routine based upon

165   Appendix A of Bohren and Huffman (1983),[5] with the refractive index ($n = m + ik$) treated as the

166   fitted parameter. The best agreement was found to be for a refractive index of $(1.63 \pm 0.02) +$

167    $(0.18 \pm 0.01)i$ (χ^2_{min} = 11.48, χ^2_{crit} = 12.592, $N = 8$) and $(1.70 \pm 0.02) + (0.28 \pm 0.01)i$ (χ^2_{min} =

168   22.65, χ^2_{crit} = 15.507, $N = 9$) at $\lambda = 405$ nm and 660 nm, respectively. These measured refractive

169   indices correlate well with others found in the literature: $1.78 + 0.19i$ ($\lambda = 360$ nm)[6], $1.70 + 0.31i$

170   ($\lambda = 532$ nm)[7], $1.72 + 0.28i$ ($\lambda = 532$ nm)[8] and $1.7 + 0.24i$ ($\lambda = 670$ nm)[9].
171

172   **Figure S25:** Fit of nigrosin refractive index at $\lambda = 405$ and $n = 1.63 + 0.18i$. Inset shows the χ^2
173   minimization of the data. Error bars are 2σ.

Figure S26: Fit of nigrosin refractive index at $\lambda = 660$ and $n = 1.70 + 0.28i$. Inset shows the χ^2 minimization of the data. Error bars for 2σ measurement uncertainty have been included but are smaller than the corresponding data points.

For the real component of nigrosin's refractive index, we assumed that m varied linearly between 405 nm and 660 nm. For wavelengths longer than 660 nm, we assumed m was equal to 1.70 (the $\lambda = 660$ nm value).

In order to calculate the imaginary component of the refractive index for nigrosin across the 16 wavelengths measured, the UV-Vis absorption spectrum of 5.0×10^{-3} mg mL^{-1} nigrosin solution was measured under acidic (0.01 M H$_2$SO$_4$), basic (0.01 M NaOH), and neutral (DI H$_2$O only) conditions. From the average measured aerosol effective density (1.34 g cm^{-3}) the solution MAC spectrum was calculated using the Beer-Lambert law:

$$\text{MAC} = \frac{A}{cl} \tag{S8}$$

where A, c and l are the UV-Vis absorption, mass concentration and path length, respectively.

188

Figure S27: MAC spectrum of 5.0 x 10^{-3} mg mL^{-1} nigrosin solution in acidic (red), basic

190 (green) and DI H$_2$O (blue). Black circles correspond to the calculated solution MAC from

191 measured refractive indices at $\lambda = 405$ nm and 660 nm.

192 From the calculated refractive indices at $\lambda = 405$ nm and 660 nm, the MAC of a 1 nm particle

193 was calculated and compared to the measured UV-Vis MAC; i.e. the MAC of the 1 nm particle

194 and solution should be comparable; i.e. Rayleigh limit of particle absorption.[10] The best

195 agreement was obtained between the basic absorption spectrum and MAC. The imaginary

196 component of the refractive index was extrapolated from the basic solution spectrum assuming

197 that the nigrosin solution behaves as a bulk material, the absorption coefficient ($\alpha_{abs,bulk}$), the

198 imaginary component of the refractive index (k) and the wavelength can be related by[5]

199 $$\alpha_{abs,bulk} = \frac{4\pi k}{\lambda} \tag{S9}$$

200 Thus, it follows that

201 $$\frac{\alpha_{\lambda_1}}{\alpha_{\lambda_2}} = \frac{k_1 \lambda_2}{k_2 \lambda_1} = \frac{A_{\lambda_1}}{A_{\lambda_2}} \tag{S10}$$

202 The calculated imaginary component of the refractive index can be seen as the in Fig. S28.

204 **Figure S28:** Calculated real (black) and imaginary (red) components of nigrosin's refractive

205 index as a function of wavelength.
