### 1. General information

Unless otherwise stated, analytical grade commercial reagents and solvents were used as received. Styrenes were bought from Alfa Aesar, Acros and Aldrich. Analytical thin layer chromatography (TLC) was performed by using commercially prepared 100–400 mesh silica gel plates (GF254) and visualization was effected at 254 nm. <sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded on a Bruker Avance 400 MHz NMR spectrometer (400 MHz for <sup>1</sup>H, 100 MHz for <sup>13</sup>C). CDCl<sub>3</sub> was used as the solvent with TMS as the internal standard, and the chemical shifts are referenced to signals at 7.26 and 77.0 ppm, respectively. Mass spectra were recorded on a Shimadzu GCMS-QP5050A spectrometer at an ionization voltage of 70 eV equipped with a DB-WAX capillary column (internal diameter: 0.25 mm, length: 30 m). HRMS analysis was performed in a MAT95XP high resolution mass spectrometer. IR spectra were obtained either as potassium bromide pellets or as liquid films between two potassium bromide pellets with a Bruker Vector 22 spectrometer. Melting points were measured with a Buchi B-545 melting point instrument.

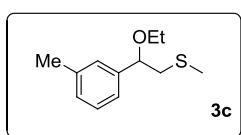

### 2. General procedure for the synthesis of β-alkoxy methylsulfides

In a typical experiment, NH<sub>4</sub>I (3.0 equiv.), olefin (1.0 mmol), ROH (or H<sub>2</sub>O for **3aa**) (2.0 equiv.), and DMSO (2.5 mL) were added to a 10 mL seal tube in sequence. The seal tube was sealed with a Teflon lined cap, and the reaction mixture was stirred at 125 °C for 26 h. After cooled to room temperature, the reaction mixture was decolorized with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, and then washed with distilled water (50 mL) and extracted with ethyl acetate (4 mL × 3). The organic layer was dried over MgSO<sub>4</sub> and concentrated under vacuum. The residue was purified by column chromatography on silica gel with petroleum ether-ethyl acetate (100:1) to give desired product.
