## SI-1 Details of Synthesis and Characterizations

Figure S1. Synthetic flow chart of the micro-mesoporous SrTiO$_3$ photocatalyst.

Table S1. The synthesis details of other materials

Samples	Starting Materials [#,*]	Reaction Conditions
Cr doped SrTiO$_3$	0.05 mmol Cr(NO$_3$)$_3$•9H$_2$O 4.95 mmol Sr(CH$_3$COO)$_2$•0.5H$_2$O 5.00 mmol [(CH$_3$)$_2$CHO]$_4$Ti	3 M NaOH aqueous solution, 170 ^{o}C, 24 h
La,Cr codoped SrTiO$_3$	0.05 mmol La(NO$_3$)$_3$•6H$_2$O 0.05 mmol Cr(NO$_3$)$_3$•9H$_2$O 4.95 mmol Sr(CH$_3$COO)$_2$•0.5H$_2$O 4.95 mmol [(CH$_3$)$_2$CHO]$_4$Ti	3 M NaOH aqueous solution, 170 ^{o}C, 24 h
Li$_2$TiO$_3$	20 mmol CH$_3$COOLi 10 mmol [(CH$_3$)$_2$CHO]$_4$Ti	2 M NaOH + 1 M LiOH aqueous solution, 150 ^{o}C, 24 h
Na$_2$Ti$_3$O$_7$	10 mmol CH$_3$COONa 10 mmol [(CH$_3$)$_2$CHO]$_4$Ti	1 M NaOH aqueous solution, 150 ^{o}C, 24 h
K$_2$Ti$_4$O$_9$	10 mmol CH$_3$COOK 10 mmol [(CH$_3$)$_2$CHO]$_4$Ti	1 M KOH + 1 M K$_2$CO$_3$ aqueous solution, 150 ^{o}C, 24 h

[#] All the samples were added 40 wt% SiO$_2$ nano-template in the sol-gel process.
[*] The Cr(NO$_3$)$_3$•9H$_2$O and La(NO$_3$)$_3$•6H$_2$O were dissolved in ethylene glycol to prepare a certain concentration solutions in advance for precise doping. All the acetates were dissolved in glacial acetic acid and the [(CH$_3$)$_2$CHO]$_4$Ti was dissolved in ethanol for the followed sol-gel process.

# SI-2 Characterizations of SiO$_2$ Nano-template

Figure S2. Characterizations of SiO$_2$ nano-template. (a) XRD pattern. (b) TEM image. (c) Nitrogen adsorption–desorption isotherms and linear part for BET surface area calculation (inset). (d) Pore distribution and cumulative pore volume analyzed by DFT simulation; HPW, half pore width; CPV, cumulative pore volume.

SI-3 Microstructural Feature and Chemical Compositions of Nanoporous SrTiO$_3$

Table S2. Pore types and distribution percentages

Samples	Micropore / % HPW < 1 nm	Mesopore I / % 1 nm < HPW < 10 nm	Mesopore II / % 10 nm < HPW
STO-SiO$_2$-10%	0	49.7	50.3
STO-SiO$_2$-20%	1.1	65.3	33.6
STO-SiO$_2$-30%	3.9	71.8	24.3
STO-SiO$_2$-40%	3.7	77.4	18.9
STO-SiO$_2$-50%	6.0	71.6	22.4
STO-SiO$_2$-60%	5.6	75.4	19.0
STO-SiO$_2$-70%	7.2	73.4	19.4
STO-SiO$_2$-80%	8.8	73.6	17.6
STO-SiO$_2$-90%	5.7	60.9	33.4

Table S3. Chemical Compositions of as-prepared SrTiO$_3$ samples

Samples	Elements / wt%[#]			Molar Ratio of Sr : Ti
	Sr	Ti	Si	
STO-SiO$_2$-10%	41.2	22.6	1.90	0.996 : 1.000
STO-SiO$_2$-30%	40.0	21.8	3.08	1.002 : 1.000
STO-SiO$_2$-50%	38.9	21.2	3.95	1.002 : 1.000
STO-SiO$_2$-90%	37.0	19.8	5.08	1.007 : 1.000

[#] The weight percentages of elements were measured by ICP-OES.
SI-4 Calculation of FWHM in XRD Pattern

Figure S3. XRD patterns of STO-SiO$_2$-30%.

Taking the STO-SiO$_2$-30% sample as an example to introduce the calculation of the FWHM in the XRD pattern,

for all the SrTiO$_3$ samples in this study, we took the (110) peak as an index peak;

firstly, enlarging the (110) peak of XRD pattern, then marking the peak center and background as shown by the black dash lines;

secondly, recording the peak intensity, I_{peak}, as presented by the red line, then recording the background intensity (the crossing point of two black dash lines), $I_{background}$ as presented by the blue line;

thirdly, calculating the intensity of the half maximum, $I_{hm} = (I_{peak} - I_{background})/2 + I_{background} = (1762 - 231)/2 + 231 = 997$;

finally, marking the height of the half maximum (as shown by the magenta line) and measuring the FWHM = 0.720 °.

# SI-5 Influence of SiO_2 Nano-template on Crystallization

Figure S4. XRD patterns of $SrTiO_3$ samples without (a) and with (b) SiO_2 nano-template in synthesis. The dash lines are the baselines of each samples, where absolute intensities = 0

Table S4. Crystallinity variation of $SrTiO_3$ samples without and with SiO_2 nano-template in synthesis under different reaction times.

Reaction Time	*FWHM* of STO-SiO$_2$-0% / °	*FWHM* of STO-SiO$_2$-90% / °
10 min (55 °C)[#]	0.66	(amorphous)
150 °C 6 h	0.19	1.98
150 °C 12 h	0.18	2.04
150 °C 24 h	0.18	1.84

[#]Before hydrothermal reaction, after adding NaOH (12 g) into the STO-gel suspension solution (100 mL), the highest temperature of solution reached 55 °C.

A contrast study of the reaction-time-dependent crystallinity variation between the STO-SiO$_2$-0% and STO-SiO$_2$-90% samples was carried out (Figure S4 and Table S4). According to the value change of FWHM, the sample without nano-template (STO-SiO$_2$-0%) could crystallize quickly and reach growth equilibrium after 12 h hydrothermal treatment; in contrast, the sample with 90% nano-template (STO-SiO$_2$-90%) underwent a very slow growing during the whole synthesis process. Thereby, it was found that the SiO_2 nano-template dominated the crystallization rate of $SrTiO_3$.

Table S5. Conversion percentages of Si element from the SiO_2 to the Na_2SiO_3 under different reaction times

Reaction Time	CP_{HRS}[#] / %	TCP* / %
0 min [#]	0.0	-
10 min (55 °C)*	31.9	-
150 °C 2 h	60.1	-
150 °C 6 h	60.5	-
150 °C 12 h	63.1	-
150 °C 24 h	67.5	76.2

[#] CP_{HRS}, conversion percentage in hydrothermal reaction solution. The hydrothermal reaction solution was measured the Si concentration ($[Si]_{HRS}$) by ICP-AES. The $CP_{HRS} = [Si]_{HRS} * V_{HRS} / m(Si)_{template} * 100\%$.

* TCP, total conversion percentage. After hydrothermal reaction and separating samples from hydrothermal reaction solution, the samples were treated by ultrasonic-cleaning with ultrapure water and centrifugally separated. The solutions that contained the Na_2SiO_3 desorbed from the sample surface were collected and mixed with the hydrothermal reaction solution, and then the mixed solution was concentrated and measured the Si concentration ($[Si]_{HRS+OSS}$) by ICP-AES. The $TCP = [Si]_{HRS+OSS} * V_{concentrated} / m(Si)_{template} * 100\%$.

In NaOH aqueous solution, the SiO_2 reacts with NaOH to form Na_2SiO_3, and then the Na_2SiO_3 can dissolve into water. The conversion of Si element from SiO_2 to Na_2SiO_3 in the present synthesis can be detected via the inductance coupling plasma-optical emissive spectrum (ICP-OES) measurement for the reaction solution (Table S5). For the STO-SiO_2-90% sample, at initial stage of synthesis (after adding NaOH into the precursor suspension solution and during beginning of the hydrothermal reaction), the conversion percentage of Si element from SiO_2 to Na_2SiO_3 in hydrothermal reaction solution, CP_{HRS}, rapidly increased from 0% to 60.1%, because the big organic frame of precursor deconstructed into a large amount of sub-micro particles (tens to hundreds of nanometers in size) and released a lot of SiO_2 into solution. The process was accompanied with the formation of a huge number of tiny crystal nucleuses. However, the remnant SiO_2 nano-templates in the sub-micro particles dissolved to generate Na_2SiO_3 and then dispersed from the inner of pores and the surface into solution very slowly, which could be supported by the evidence that the CP_{HRS} slightly increased from 60.1% to 67.5% during 2 h to 24 h of hydrothermal reaction. Furthermore, when we cleaned the STO-SiO_2-90% sample under 24 h hydrothermal treatment carefully, and then collected the hydrothermal solution and all the cleaning solution to measured ICP-OES for calculating the total conversion percentage of Si element from SiO_2 to Na_2SiO_3, TCP (Table S5). It reached 76.2% which was obviously higher than the CP_{HRS}, indicating that the slow increase of Si element in hydrothermal solution with increasing the reaction time indeed resulted from the slow release of Na_2SiO_3 from the surface and inner of $SrTiO_3$ particle.

# SI-6 Characterizations of Commercial Nano-SrTiO₃

Figure S5. Characterization of commercial nano-sized SrTiO₃ (C-Nano-STO for short; No.329-43442, Wako, Japan). (a) XRD pattern. (b) TEM image. (c) Nitrogen adsorption–desorption isotherms and linear part for BET surface area calculation (inset). SI-8 Characterizations of Nanoporous Doped SrTiO₃

To exemplify our synthetic process is available in the case of doped $SrTiO_3$, we fabricated the Cr doped $SrTiO_3$ (Cr is doped into the Sr site of $SrTiO_3$) and La, Cr codoped $SrTiO_3$ (La and Cr are doped into the Sr and Ti sites of $SrTiO_3$, respectively). The detailed synthetic conditions are listed in Table S1.

The doped $SrTiO_3$ samples crystallize in the same symmetry as the undoped $SrTiO_3$ (Figure S8a) but extend their light absorption into visible region (Figure S8b). The hysteresis loops in the N_2 adsorption-desorption isotherms (Figure S9a, S10a) indicate that the porous structures exist in both Cr doped $SrTiO_3$ and La, Cr codoped $SrTiO_3$. Similar to the undoped $SrTiO_3$, the major pores in these samples are also HPW < 10 nm. However, the codoped material has more uniform pore than the mono-doped case (Figure S9b, S10b). Both they contain a little amount of micropore with a main size of 2 − 5 Å (Figure S9c, S10c). These doped samples are nanocrystal-constructed microspheres with average diameters of about 200 and 400 nm for Cr doped $SrTiO_3$ and La, Cr codoped $SrTiO_3$, respectively (Figure S9d,e, S10d,e). The resolved lattice fringes observed from the edges of microspheres indicate the samples are crystallized (Figure S9f, S10f).

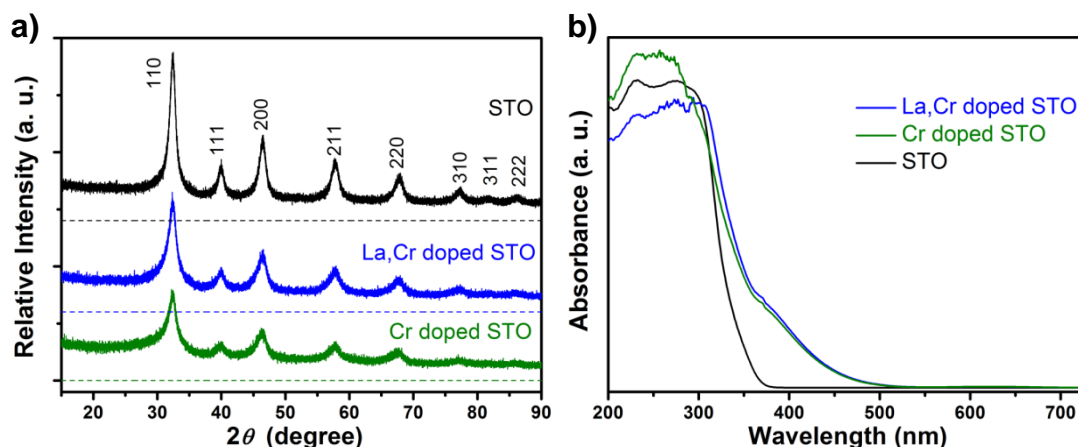

Figure S8. XRD patterns (a) and UV-visible absorption spectra (b) of $SrTiO_3$, Cr doped $SrTiO_3$, and La,Cr doped $SrTiO_3$. (The $SrTiO_3$ reference sample was synthesized under the similar conditions of doped $SrTiO_3$ samples; 40% SiO_2 nano-template, 3 M NaOH, 170 °C, 24 h.)

SI-9 Characterizations of Nanoporous Alkali-metal Titanates

To exemplify our synthetic process is applicable for the alkali-metal titanates, we synthesized three typical materials, such as Li_2TiO_3, $Na_2Ti_3O_7$, and $K_2Ti_4O_9$. The detailed synthetic conditions are listed in Table S1.

The Li_2TiO_3 grows in a monoclinic symmetry (Figure S11a). The N_2 adsorption-desorption isotherm shows a typical hysteresis loop (Figure S11b), indicating this material possesses the porous structure. The HPW of these pores mainly distributes below 10 nm, but the micro-pore structure is not detected (Figure S11c). The BET surface area of this sample reaches 215.2 m^2/g. The TEM images present that this material are irregular particles which are loosely aggregated by a number of nanocrystals (Figure S11d), and thus some of these nanocrystals easily depart from the assembled particle to form monodispersed status (Figure S11e-f).

The $Na_2Ti_3O_7$ also crystallizes in a monoclinic symmetry (Figure S12a). A typical hysteresis-loop figure in the N_2 adsorption-desorption isotherm reveals the sample contains porous structure (Figure S12b). The material shows highly uniform pore-size distribution, and the HPW of the major pores is smaller than 5 nm, but the micro-pore structure is not observed (Figure S12c). The TEM images exhibit that this material are irregular particles with size from several hundred nanometers to several micrometers (Figure S12d).

The $K_2Ti_4O_9$ grows as a monoclinic-phase structure (Figure S13a). The contained porous structure can be revealed by the typical hysteresis loop in the N_2 adsorption-desorption isotherm (Figure S13b). This material also presents highly uniform pore size; the HPW mainly distributes below 5 nm (Figure S13c), and the micro-pore structure with a major HPW between 2 and 4 Å is detected (Figure S13d). The TEM images indicates that the sample is some aggregates of layered nanocrystals (Figure S13e,f; blue arrows mark the layered micro-structures); the particle size is from several hundred nanometers to several micrometers.
