## General procedures

With the exception of the synthesis of starting materials, all reactions and manipulations were carried out under an atmosphere of dry, $\mathrm{O}_{2}$-free nitrogen using standard double-manifold techniques with a rotary oil pump. An argon-filled glove box was used to manipulate solids including the storage of starting materials, room temperature reactions, product recovery and sample preparation for analysis. Molecular sieves $(4 \AA)$ were dried at $120^{\circ} \mathrm{C}$ for 24 h prior to use. All solvents (toluene, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{THF}$, pentane, hexane) were dried by employing a solvent purification system MB SPS-800, degassed and stored over molecular sieves under a nitrogen atmosphere. Deuterated solvents were dried over molecular sieves before use. Chemicals were purchased from commercial suppliers and used as received. $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ was prepared based on a slightly modified synthesis reported in the literature. ${ }^{[1]}$ The IPr* ligand was prepared according to the literature procedure. ${ }^{[2]}{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}{ }^{11} \mathrm{~B}$ and ${ }^{19} \mathrm{~F}$ NMR spectra were recorded on a Avance III, Avance 400, Avance-III-300, Avance DRX-300, Avance 500 or Avance 600. Chemical shifts are expressed as parts per million (ppm, $\delta$ ) downfield of tetramethylsilane (TMS) and are referenced to $d_{8}$-toluene, $d_{6}$-benzene, $d_{8}$-THF, $\mathrm{CDCl}_{3}(7.26 / 77.16$ $\mathrm{ppm})$ and $\mathrm{CD}_{2} \mathrm{Cl}_{2}(5.32 / 53.80 \mathrm{ppm})$ as internal standards. NMR spectra were referenced to $\mathrm{CFCl}_{3}$ $\left({ }^{19} \mathrm{~F}\right)$ or 1,2-difluorobenzene ( -139 ppm ) and $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O} / \mathrm{CDCl}_{3}\left({ }^{11} \mathrm{~B}\right)$. The description of signals include: $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{m}=$ multiplet and $\mathrm{br} .=$ broad. All coupling constants are absolute values and $J$ values are expressed in Hertz (Hz). Mass spectra (MS and HRMS) were determined in the chemistry department of the University Heidelberg under the direction of Dr. J. Gross. FAB (+) spectra were obtained using a JEOL JMS-700 spectrometer. For the FAB-matrix, 3nitrobenzyl alcohol (NBA) or o-nitrophenyl octyl ether (NPOE) was used. For ESI (+) spectra, a ApexQe FT-ICR-MS spectrometer was used. Infrared Spectroscopy (IR) was processed on an FT-IR (IF528), IR (283) or FT-IR Vektor 22.

## (1,3-bis(2,6-diisopropylphenyl)-2,3-dihydro-1H-imidazol-2-yl)(prop-1-yn-1-yl)gold (1)

(Idipp) $\mathrm{AuCl}(400 \mathrm{mg}, 0.64 \mathrm{mmol})$ was dissolved in THF $(15 \mathrm{~mL})$ and cooled to $-78^{\circ} \mathrm{C}$. At this temperature 1-propynylmagnesium bromide ( $3.9 \mathrm{~mL}, 1.93 \mathrm{mmol}, 3.0$ eq., 0.5 M in THF) was added, stirred for 2 h and then warmed up to room temperature and stirred for additional 12 h . Aqueous saturated $\mathrm{NaHCO}_{3}$ solution $(10 \mathrm{~mL})$ was added and the aqueous phase extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{x}$ 30 mL ). The combined organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and the solvent removed under reduced pressure. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ pentane affords the product as white solid ( 382 mg , $94 \%)$. The spectral data is in accordance with literature data. ${ }^{[3]}$

(Idipp) $\mathrm{AuCl}(100 \mathrm{mg}, 0.0161 \mathrm{mmol})$ and phenyl acetylene $(17 \mathrm{mg}, 0.170 \mathrm{mmol})$ were placed in a Schlenk bomb along with $\mathrm{EtOH}(20 \mathrm{~mL})$ and to this $\mathrm{NaOMe}(9 \mathrm{mg}, 0.170 \mathrm{mmol})$ in $\mathrm{EtOH}(5 \mathrm{~mL})$ was added. The reaction was heated to $80^{\circ} \mathrm{C}$ for 1 h and upon cooling to room temperature the solvent was removed in vacuo. The resulting residue was taken up in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and filtered through Celite.

The resulting solution was then evaporated to dryness affording the colorless product ( 99 mg , $0.144 \mathrm{mmol}, 85 \%)$.

The solution was stirred for 5 min and then $100 \mu \mathrm{~L}$ of this solution ( $0.5 \mathrm{~mol} \%$ ) was added to a substrate solution of 2-methyl-5-((prop-2-yn-1-yloxy)methyl)furan ( 0.2 mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(0.5 \mathrm{~mL})$ containing $1,3,5$-tristertbutylbenzene $(16.4 \mathrm{mg}, 0.067 \mathrm{mmol})$ as internal standard. ${ }^{1} \mathrm{H}$ NMR spectra were measured as indicated (see below).

## X-ray data

X-ray data (cif) can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

X-ray crystal structure analyses were measured on a Bruker Smart CCD or Bruker Smart APEX instrument using Mo-K $\alpha$ radiation. Diffraction intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using $\operatorname{SADABS}^{[6]}$ based on the Laue symmetry of reciprocal space. Heavy atom diffractions were solved by direct methods and refined against $F^{2}$ with the full matrix least square algorithm using the SHELXL (Version 2014-3) software. ${ }^{[7]}$ Hydrogen atoms were either isotropically refined or calculated. The structures were solved and refined using the SHELXTL software package.

## University of Toronto X-Ray Data

X-Ray Data Collection and Reduction

Crystals were coated in Paratone-N oil in the glovebox, mounted on a MiTegen Micromount and placed under an $\mathrm{N}_{2}$ stream, thus maintaining a dry, $\mathrm{O}_{2}$-free environment for each crystal. The data were collected on a Kappa Bruker Apex II diffractometer. Data collection strategies were determined using Bruker Apex 2 software and optimized to provide $>99.5 \%$ complete data to a $2 \theta$ value of at least $55^{\circ}$. The data were collected at $150( \pm 2) \mathrm{K}$ for all. The data integration and absorption correction were performed with the Bruker Apex 2 software package. ${ }^{[8]}$

X-Ray Data Solution and Refinement

Non-hydrogen atomic scattering factors were taken from the literature tabulations. ${ }^{[9]}$ The heavy atom positions were determined using direct methods employing the SHELX-2013 direct methods routine. The remaining non-hydrogen atoms were located from successive difference Fourier map calculations. The refinements were carried out by using full-matrix least squares techniques on F , minimizing the function $\omega(\mathrm{Fo}-\mathrm{Fc}) 2$ where the weight $\omega$ is defined as $4 \mathrm{Fo} 2 / 2 \sigma$ (Fo2) and Fo and Fc are the observed and calculated structure factor amplitudes, respectively. In the final cycles of each refinement, all nonhydrogen atoms were assigned anisotropic temperature factors in the absence of disorder or insufficient data. In the latter cases atoms were treated isotropically. C-H atom positions were calculated and allowed to ride on the carbon to which they are bonded assuming a C-H bond length of $0.95 \AA$. H-atom temperature factors were fixed at 1.20 times the isotropic temperature factor of the Catom to which they are bonded. The H -atom contributions were calculated, but not refined. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities in each case were of no chemical significance.

## Computational details

## Computational methods

All calculations were performed by employing the Gaussian09 program package. ${ }^{[10]}$ The theoretical approach is based on density functional theory (DFT), ${ }^{[11,12]}$ in combination with the hybrid B3LYP functional, ${ }^{[6]}$ together with a relativistic pseudopotential for Au. ${ }^{[13]}$ The pseudopotential basis set and the all-electron basis sets for the other light elements ( $\mathrm{H}, \mathrm{C}, \mathrm{B}, \mathrm{F}$ ) were of cc-pVDZ quality for all systems. Geometries were fully optimized without symmetry restrictions. All intermediates were uniquely characterized by occurrence of none imaginary frequency. Gibbs free energies are calculated for standard temperature and pressure $(298.15 \mathrm{~K}, 1 \mathrm{~atm})$ and are corrected in respect to zero point energies which are calculated based on gas phase frequency calculations. 3D structures were generated with the program package CYLview, 1.0b; Legault, C. Y., Université de Sherbrooke, 2009 (http://www.cylview.org).

Preliminary theoretical studies of the $\sigma-B / \pi-A u$ alkynyl borate species at the B3LYP/cc-pVDZ level of theory indicate that the thermodynamics of a $\mathrm{C}_{6} \mathrm{~F}_{5}$-group transfer from boron to gold versus boron to carbon are very close in energy $\left(\Delta \mathrm{G}_{\mathrm{B}-\mathrm{Au}}=-12.3 \mathrm{kcal} / \mathrm{mol}\right.$ vs. $\left.\Delta \mathrm{G}_{\mathrm{B}-\mathrm{C}}=-12.0 \mathrm{kcal} / \mathrm{mol}\right)$ suggesting that a kinetic barrier precludes concerted $1,2-\mathrm{C}_{6} \mathrm{~F}_{5}$ boron to carbon shift.
