All commercial reagents were used as purchased. FT–IR spectra were recorded on a Bruker Vertex spectrophotometer. ^1H and ^{13}C NMR spectra were recorded on a Bruker Avance 400 spectrometer or a Bruker Avance 300 spectrometer. The mesophase identification was based on microscopic examination of the textures formed by samples between two glass plates. NIKON and OLYMPUS BH–2 polarizing microscopes equipped with a LINKAM THMS600 hot stage were used. The temperatures and enthalpies of the phase transitions were determined by calorimetric measurements performed with DSC TA Instrument Q–20 and Q–2000 systems. Thermogravimetric analysis (TGA) was performed using a TA Q5000IR instrument at a heating rate of 10 °C /min under a nitrogen atmosphere. The X–ray investigations on non–oriented samples were carried out in Lindemann capillary tubes (diameter: 0.9 or 1 mm) using a PINHOLE (ANTON–PAAR) film camera. XPS instrument is a Kratos Aris Ultra DLD. The X–ray source was run at 12 kV and 10 mA. All core–level spectra were referenced to the C 1s neutral carbon peak at a binding energy of 285.0 eV in order to compensate for surface charge effects. The pressure in the analysis chamber was maintained under ultrahigh vacuum below 10^{-9} mbar.

X–ray quality single crystals were obtained by slow evaporation of solutions of complexes P-Py1-10 and P-BN-10 in CH₃CN. The crystals are air stable and were mounted on the tip of a glass fibre using epoxy cement. X–ray diffraction experiments were carried out on an Oxford–diffraction Xcalibur S diffractometer. Data were collected at 150(2) K with Mo–K α radiation. Software packages XSCANS¹ and CrysAlis² were used to process data.

General Procedure for the preparation of bis(iodoethynyl)benzene

N-Iodosuccinimide (4.14 g, 36.2 mmol) and silver nitrate (0.62 g, 3.62 mmol) were added successively to a solution of corresponding diethynylbenzene (2.28 g, 18.1 mmol) in acetone. The reaction mixture was stirred at 0°C for 5 h. The crude was filtered and washed with diethylether, afterwards the solvent was removed under reduce pressure. The residue was extracted with dicloromethane (3 x 50 mL) and water (50 mL). Then, the organic layer was dried over MgSO_4 and evaporated. The pure products were recovered as yellow solids.

S7. Computational Methods

Quantum chemical calculations were performed using the Gaussian 09⁷ suite programs. Geometry optimizations were carried out in the gas phase with the B98⁸⁻¹⁰ method, employing 6-311G+(d,p)¹¹ basis set for all atoms except iodine for which the DGDZVP¹² basis set was used. Geometry optimizations were carried out without constraints, using the default convergence criteria for the Gaussian software. Vibrational frequency calculations were performed at the same level of the theory as the geometry optimization and the frequency scale factor estimated by Radom *et al*¹³ was used (0.9676). The basis set superposition error (BSSE) for noncovalent complexes was estimated using the counterpoise method of Boys and Bernardi.¹⁴ The natural bond orbital (NBO) analysis¹⁵ using the NBO module containing in Gaussian 09 program were performed on the basis of the minimized structures in order to calculate the NBO charges. The energies of interaction (ΔE_{int}) were calculated by subtracting the electronic energies of the optimized isolated partners ($E_{partner}$) of the electronic energy of the optimized noncovalent complex ($E_{complex}$), in accordance with the following equation:

$$\Delta E_{int} = E_{complex} - \sum E_{partner}$$

The obtained electronic energies of interaction were corrected for scale (0.9884)¹³ zero point differences and for basis set superposition errors.

Calculated gas-phase energy of monomers and complexes optimized with B98/6-311+G(d,p)-DGDZVP and Cartesian coordinates of calculated structures.
