2D NMR (HMBC) of 6 in C₆D₆ (Part 2)

2. X-ray structure determination

Single crystals suitable for X-ray diffraction were obtained as described in the synthetic procedures. The crystallographic data were collected with a Bruker 6 kW APEX Smart and a Bruker 12 kW APEX Smart 6000 diffractometer. The crystals were coated with a perfluoropolyether, picked up with a glass fiber and immediately mounted in the cooled nitrogen stream of the diffractometer. The structures were solved by direct methods and refined with the program SHELXL-97 by a full-matrix least-squares method based on F^2 . Crystal data, data collection parameters and structure refinement details are given in Table 1.

Table 1. Crystal data, data collection, and structure refinement.

3. Computational Section

General. The computational study was performed using Gaussian 09 suite of programs (Revision A.02).¹ All DFT calculations were conducted using the dispersion-corrected functional M06-2X and 6-31+G(d,p) basis set.² Frequency calculations on the computed structures confirmed the nature of the computed minima and transition states and allowed ZPE corrections on the computed energies. Small negative eigenvalues located on the methyl groups have been neglected. The computed energies reported in this work refer to the molecules in the gas phase. The computed electronic energies (E), zero point energies (ZPE) and Gibbs free energies (G) are given in atomic units. Relative energies (ΔE , $\Delta E(\text{ZPE})$) and ΔG are given in kcal·mol⁻¹.

3.1. Structural analysis of **1**

We performed a computational analysis to investigate on the stability of dimer [**1**]₂. The energies of the computed structures are reported in Table 1. Thermal corrections to enthalpy, thermal corrections to Gibbs free energy and total entropy of the computed structures are listed in Table 2.

	E	ΔE	ZPE	$\Delta E(\text{ZPE})$	G	ΔG

3.2. Reaction of [**1**]₂ with CO₂

We performed a computational analysis to investigate on the reaction of **1** (monomeric) with CO₂. We could locate, on the PES (potential energy surface), structures **vdW** and **2** as energy minima, and **TS1** as a transition state connecting **vdW** to **2**. The formation of **1** from 0.5 moles of [**1**]₂ is endoergonic ($\Delta G = 15.3$ kcal·mol⁻¹; Table 1). The computed energies for the reaction of **1** with CO₂ are reported in Table 3.

Thermal corrections to enthalpy, thermal corrections to Gibbs free energy and total entropy of the computed structures are listed in Table 4.

Table 4. M06-2X/6-31+G(d,p) thermal corrections to enthalpy (a.u.), thermal corrections to Gibbs free energy (a.u.) and total entropy (cal/mol-K) for the computed structures.

3.3. Rearrangement of CO₂ adducts

In order to rationalize the unexpected rearrangement of **2** into **3**, which we have observed in select cases, and which was also observed by Fontaine and co-workers for the CO₂-adducts, we resorted again to computational chemistry.

First, we computed the reaction pathway proposed by Fontaine *et al.*³ for the rearrangement of Me₂PCH₂AlMe₂-CO₂ adduct (**2-Me**) into the Al-carboxylate **3Me** (analogous to **3**) at M06-2X/6-31+G(d,p) level of theory. This allowed comparison of our results with the ones obtained by Fontaine *et al.* using the B3LYP functional and 6-31+G(d,p) basis set.³ The computed reaction pathway is analogous to the one shown for the rearrangement of **2** (into **3**) in Figure 3. The relative SCF energies and Gibbs free energies for the computed structures using the two different functionals are reported in Table 5. We observed deviations in the computed relative energies within ± 3 kcal·mol⁻¹. We note that the overall barrier predicted using the M06-2X functional (36.0 kcal·mol⁻¹) is even higher than the one predicted by B3LYP (34.7 kcal·mol⁻¹). We point out that such high reaction barriers contrast with the facile rearrangement observed experimentally. In fact, the complete rearrangement of **2-Me** was observed to occur in 1h at room temperature, while it was complete after only 10 minutes with **2-Ph**, for which a similar barriers were predicted.³

	ΔE (B3LYP)	ΔE (M06-2X)	ΔG (B3LYP)	ΔG (M06-2X)

Table 7. M06-2X/6-31+G(d,p) thermal corrections to enthalpy (a.u.), thermal corrections to Gibbs free energy (a.u.) and total entropy (cal/mol·K) for the computed structures.

Next, we computed the analogous reaction pathway for the rearrangement of *t*Bu₂PCH₂AlMe₂-CO₂ adduct **2** into **3**, and finally [3]₂. We note that with *tert*-butyl substituents on phosphorus (instead of Me or Ph) the CO₂ uptake is far more exothermic. Consequently, the reverse reaction, namely the dissociation of CO₂ from **2** to give **vdW** occurs with a significantly higher barrier (23.6 kcal·mol⁻¹ for **2** vs 16.2 kcal·mol⁻¹ for **2-Me**). The overall barrier for such rearrangement is of 45.2 kcal·mol⁻¹, which leads to the conclusion that the rearrangement cannot occur at room temperature *via* this mechanism. This is in agreement with the thermal stability observed for some samples of **2**, which resulted stable towards rearrangement even upon heating. The computed energies are reported in Table 8. Thermal corrections to enthalpy, thermal corrections to Gibbs free energy and total entropy of the computed structures are listed in Table 9.

3.4. Reaction of [1]₂ with *t*BuNCO

To gain a deeper understanding of the exclusive formation of **6** from the reaction of [1]₂ with *t*BuNCO, we computed the structures of all possible products that could result from P/Al addition to either the C=O or the C=N bond of *t*BuNCO, namely *Z*-**7**_{C=O}, *E*-**7**_{C=O} and **7** (shown below). Formation of *Z*-**7**_{C=O} from [1]₂ is energetically unfavored ($\Delta G = 20.3 \text{ kcal}\cdot\text{mol}^{-1}$), probably as a consequence of steric repulsion between the bulky *tert*-butyl substituent on the nitrogen atom of the isocyanate and the *tert*-butyl substituents on the phosphorus atom, while the formation of products *E*-**7**_{C=O} ($\Delta G = -9.0 \text{ kcal}\cdot\text{mol}^{-1}$) and **6** ($\Delta G = -12.6 \text{ kcal}\cdot\text{mol}^{-1}$) from [1]₂ is energetically favored, with **7** being the most stable product.

The relative energies reported in Table 10 refer to the reaction of 1 isocyanate molecules with half a molecule of [1]₂. Thermal corrections to enthalpy, thermal corrections to Gibbs free energy and total entropy of the computed structures are listed in Table 11.

3.5. Substrate assisted frustration

We have considered the possibility that the substrate induces frustration by promoting the cleave of the P–Al bond in **[1]₂**. To test this hypothesis, we calculated two CO₂-adducts (**4** and **5**) of **[1]₂** at the M06-2X/6-31+G(d,p) level of theory. The computed energies are reported in Tables 12. Thermal corrections to enthalpy, thermal corrections to Gibbs free energy and total entropy of the computed structures are listed in Table 13.
