## Contents

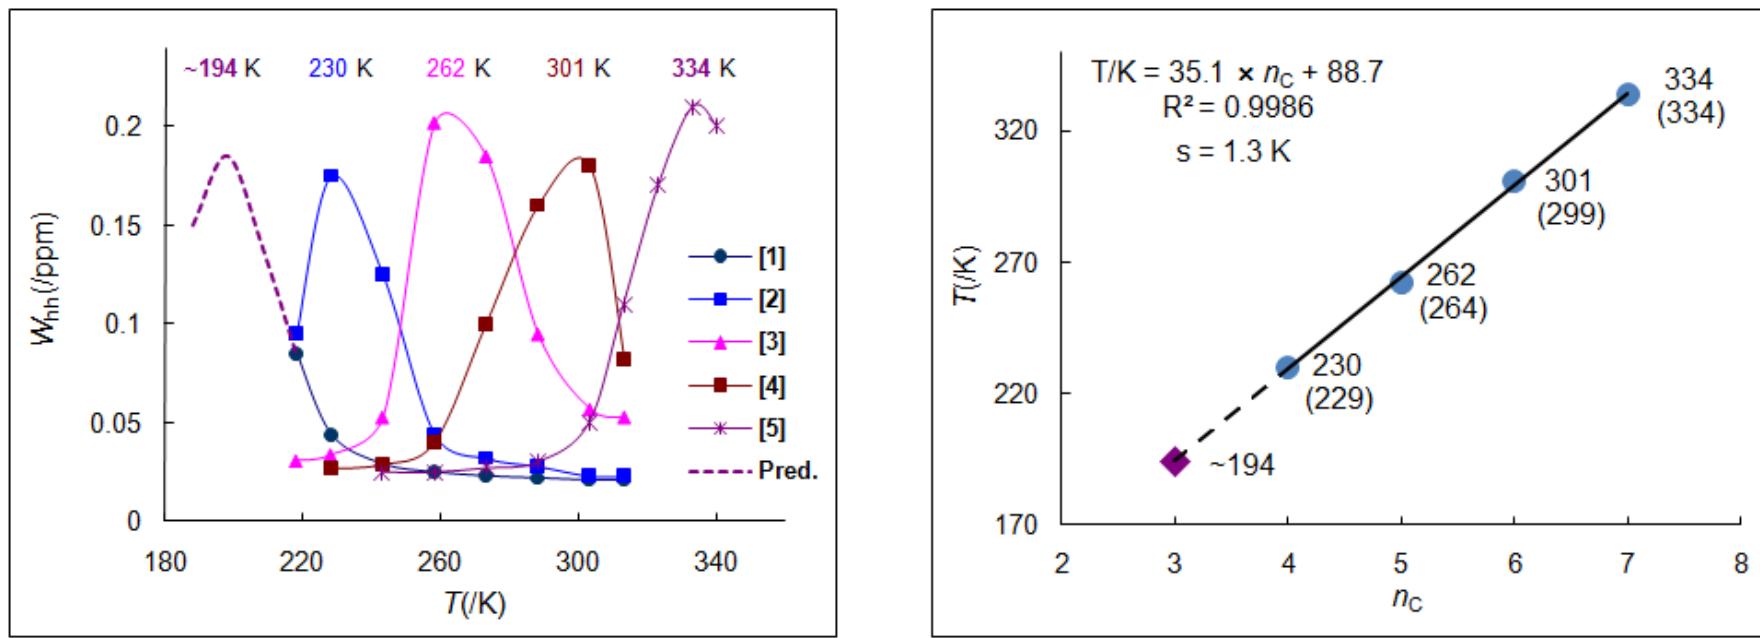

1. Acquirement of the coalescence temperature ( $T_C$ ) of the <i>meso</i> -aryl rotation .....	S2
2. Calculation of the rotational barrier ( $\Delta G^\ddagger$ ) of the <i>meso</i> -aryl groups .....	S4
3. The extraction of parameter, $d_{CC}$ .....	S5
3. The account to parameter, $d_{CC}$ .....	S5
4. The accounts to the $^1\text{H}$ NMR spectra of model compounds 1-5.....	S8
5. Correlation analysis of $\Delta G^\ddagger$ to chemical shift of the protons .....	S11
6. Variable-temperature $^1\text{H}$ NMR spectra of model compounds 1-5.....	S12
6.1 VT-NMR of compounds 1. ( $n_C = 3$ ) .....	S12
6.2 VT-NMR of compounds 2. ( $n_C = 4$ ).....	S13
6.3 VT-NMR of compounds 3. ( $n_C = 5$ ).....	S14
6.4 VT-NMR of compounds 4. ( $n_C = 6$ ).....	S15
6.5 VT-NMR of compounds 5. ( $n_C = 7$ ).....	S16

Model compounds

### 1. Acquisition of the coalescence temperature ( $T_C$ ) of the *meso*-aryl rotation

The relationship of  $T_c$  to  $W_{\text{hh}}$  of diagnostic protons  $H^7$  (left) and that of  $T_c$  to  $n_c$  in straps (right)

The coalescence temperature,  $T_c$ , of compound **1** is obtained according to the Equation 1, and the Equation is acquired through linear fitting of 4 experimental  $T_c$  to their relative  $n_c$  in straps ( $n_c$  is the number of carbon atom in the strap). The numbers denote  $T_c$  and their relative fitted values (in brackets)

$$T/K = 35.1 \times n_c + 88.7 \quad (1)$$

The predictive  $T_c$  of compound **1** ( $n_c = 3$ ) was not verified due to the poor solubility at thus low temperature (194 K).  $W_{\text{hh}}$  presents the peak width at half-height.

## 2. Calculation of the rotational barrier ( $\Delta G^\ddagger$ ) of the meso-aryl groups

$n_C$ (Compd.)	3(1)	4(2)	5(3)	6(4)	7(5)	
$\Delta G^\ddagger$ (/kJ·mol <sup>-1</sup> ) <sup>a</sup>	~37 <sup>b</sup>	45.0	51.6	60.5	67.1	
$\Delta\nu$ (/Hz)	—	127.8	123.8	87.5	100.3	$\frac{\Delta G^\ddagger}{RT_c} = 22.96 + \ln \frac{T_c}{\Delta\nu} \quad (2)$
$T_c$ (/K)	~194	230 (229)	262 (264)	301 (299)	334 (334)	

a). the value of  $\Delta G^\ddagger$  is obtained by using Equation (2)    b) the value of rotational barrier ( $\Delta G^\ddagger$ ) is also calculated by linear extension.

The value of rotational barrier ( $\Delta G^\ddagger$ ) can be also calculated by linear treatment. Because for complex, 1, the value,  $T_c/\Delta\nu$ , is near or less than 2, and the exponential term is less than 1, the term,  $(22.96 + \ln(T_c/\Delta\nu))R$ , can be viewed as a constant.

$$\text{Equation 2:} \quad \Delta G^\ddagger = (22.96 + \ln(T_c/\Delta\nu)) RT_c$$

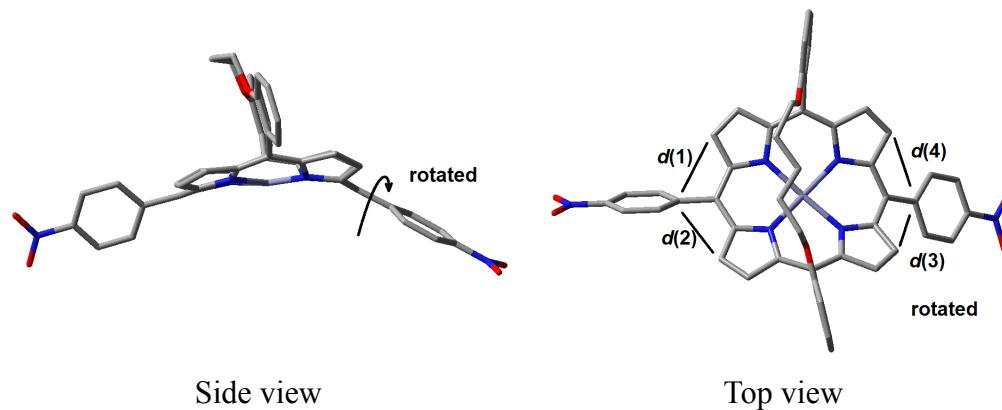

$$\Rightarrow \Delta G^\ddagger \propto T_c$$

---

### 3. The account to parameter, $d_{CC}$

In solid state, these complexes adopt a dominant arc type (or ruffle-like type) deformation, but the folding of C-O-C component in strap makes the phenyls modified by ether shift between  $\beta$ -Cs, which makes the other phenyls containing  $-NO_2$  also slightly shift from one  $\beta$ -C to another one. The 4 distances,  $d_{CC}$ , appear as four individual values,  $d_{CC}(1)$ ,  $d_{CC}(2)$ ,  $d_{CC}(3)$  and  $d_{CC}(4)$  (below Figure), the difference among them is not the deviation from error but the shift of phenyl due to macrocyclic extra deformation.

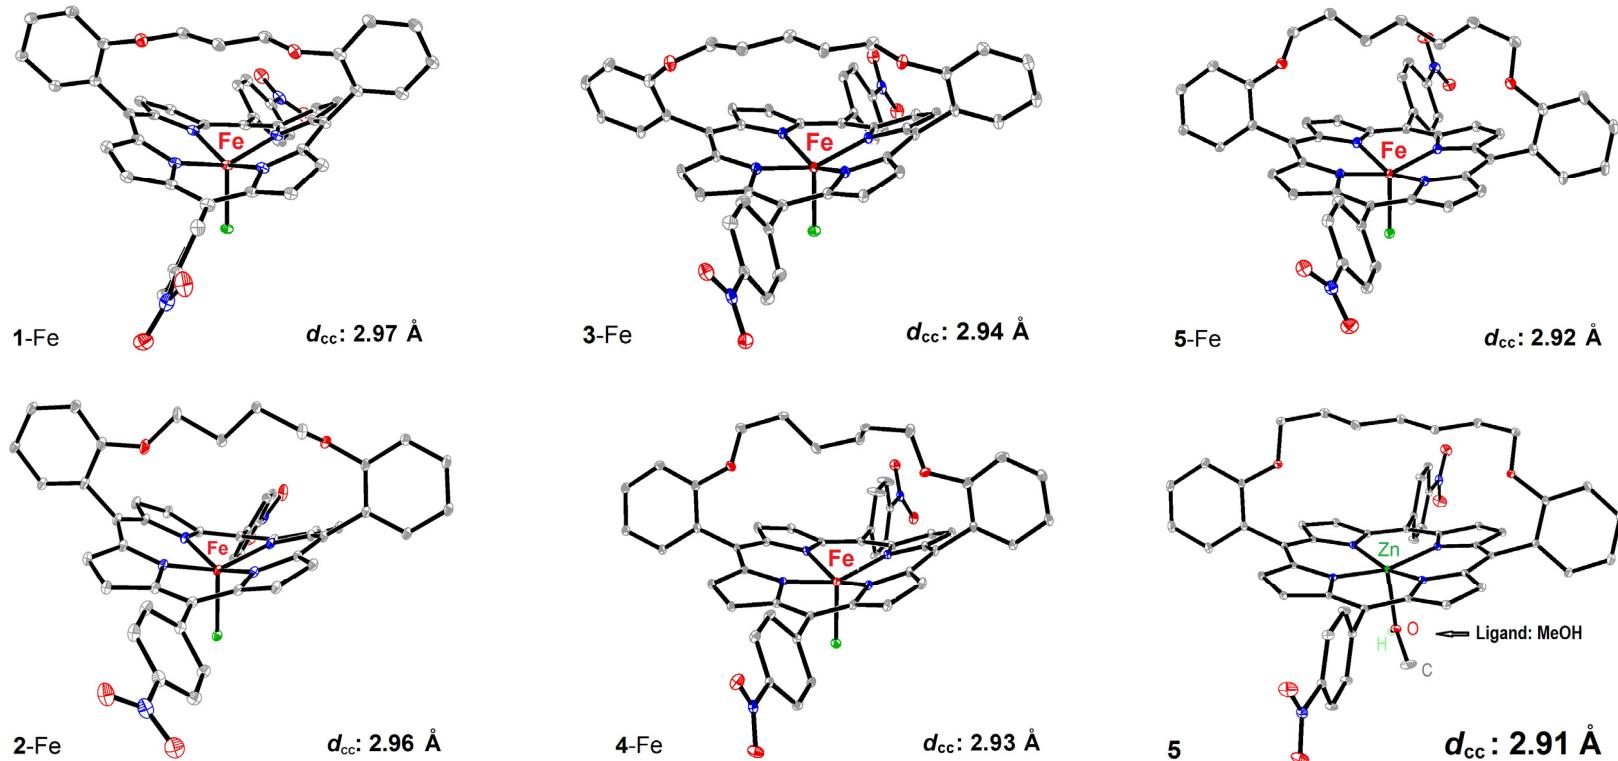

The relationship of 4  $d_{CC}$  distances can be directly reflected in computation results of rotational potential energy surface to the 5 model complexes. The 4 individual distances completely correlate each other. The computation was carried out under Gaussian 03 circumstance, and the calculation set: DFT/B3LYP/6-31G step 10°.

The computation results show that the  $d_{CC}(1)$  and  $d_{CC}(2)$  are not visibly changed and the difference between both is also invariable under the rotation forced of another aryl (below Figure). On the other hand, the mean value of 4  $d_{CC}$  is also invariable near the ground state of these complexes when the aryl is rotated. The deviation of  $d_{CC}(1)$ ,  $d_{CC}(2)$  and mean value of 4  $d_{CC}$  is very small,  $\sim 0.001$  Å around their ground states (e.g those in red cycle).

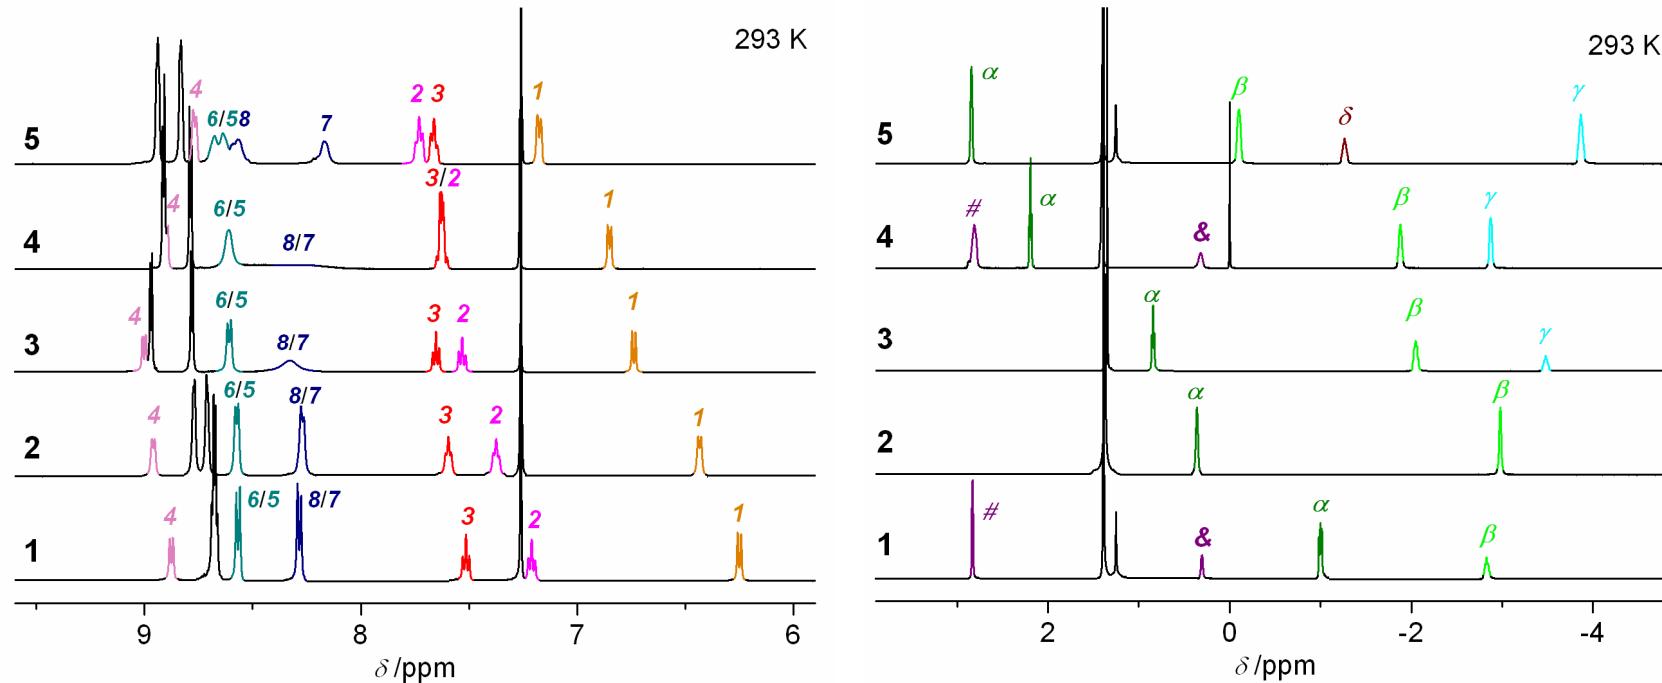

Plot of the independent  $d_{CC}$  distance to aryl rotation, step is 10 °.

The  $d_{CC}$  values of strapped metalloporphyrins **1**-Fe to **5**-Fe and **5**.

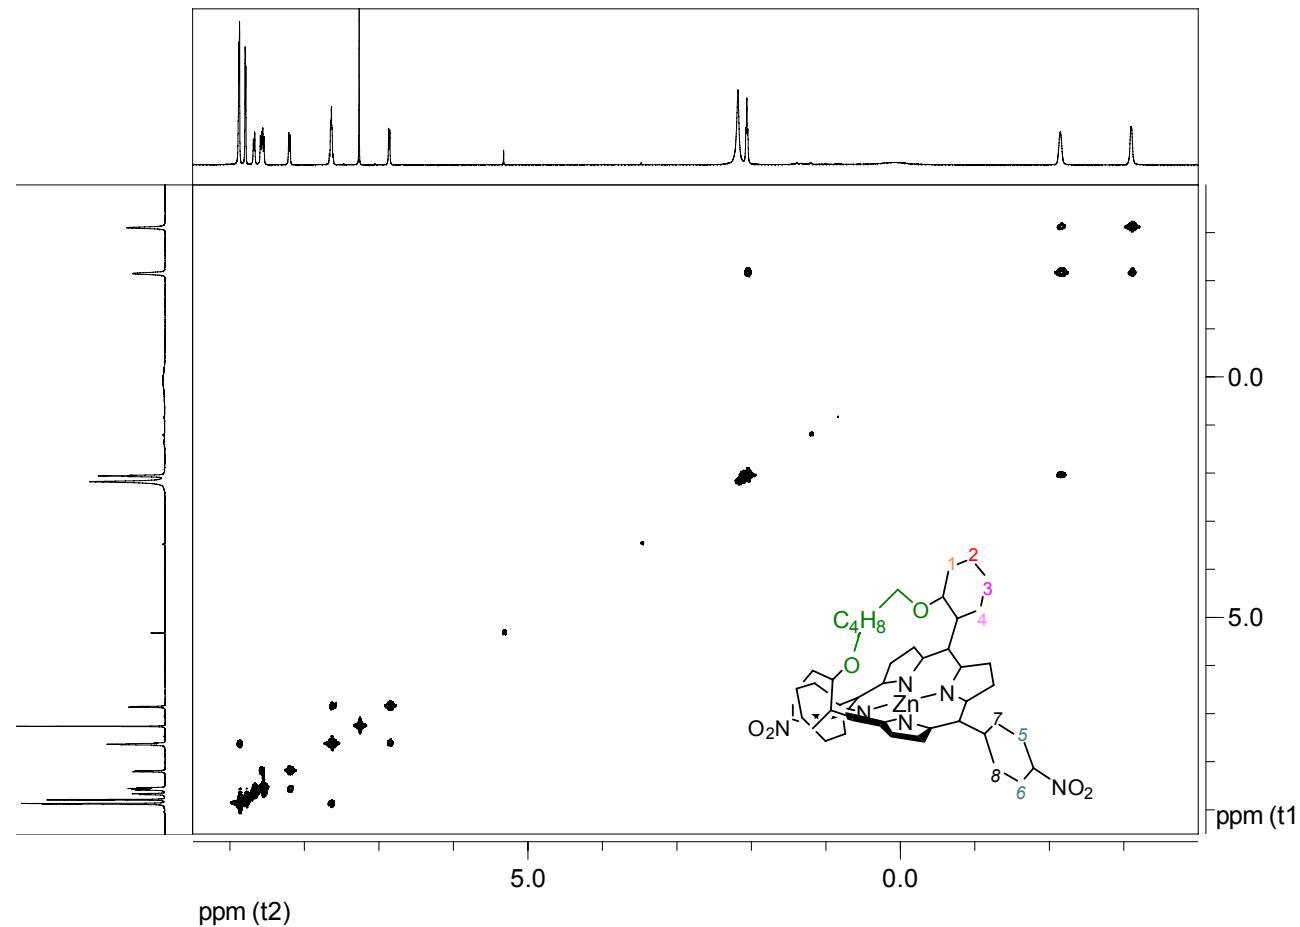

Crystal structure and parameter,  $d_{CC}$ , of strapped metalloporphyrins **1**-Fe to **5**-Fe and **5**.  
The substituents, *tert*-butyl groups, protons and solvents have been omitted for clarity.

#### 4. The accounts to the $^1\text{H}$ NMR spectra of model compounds 1 to 5

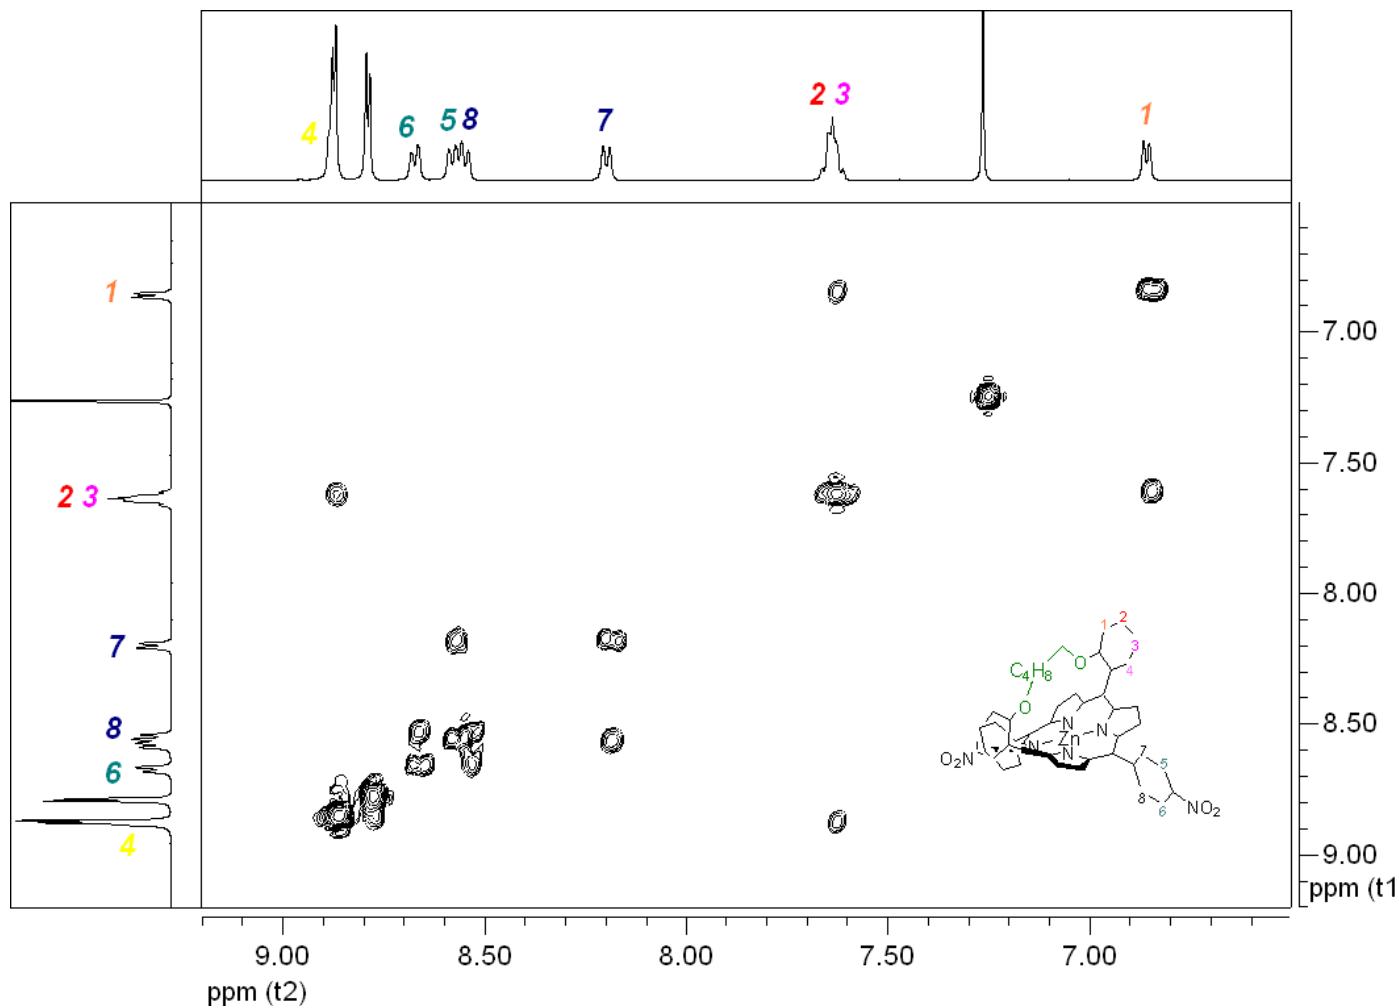

An inspection of the  $^1\text{H}$  NMR spectra of model compounds **1** to **5** reveals that there are several broad peaks at the determined temperature 293 K, especially the diagnostic signals  $\text{H}^7$  and  $\text{H}^8$  in compound **3**, **4** and **5** (above Figure). These phenomena indicate the aryl rotation has geometry dependence at a temperature.

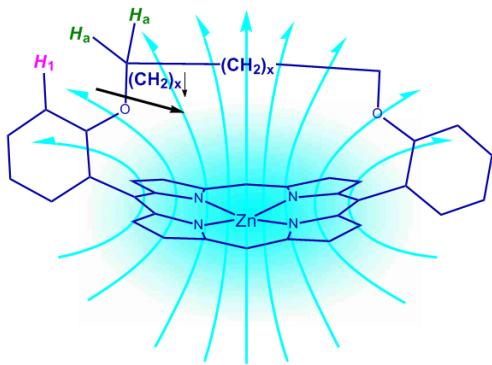

**HH COSY spectra of model compounds 4 at 228 K**

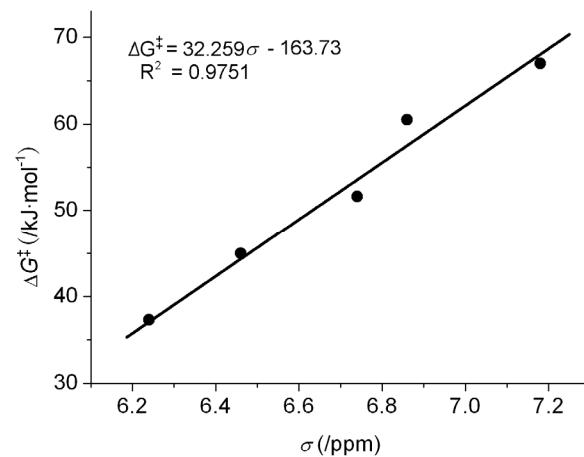

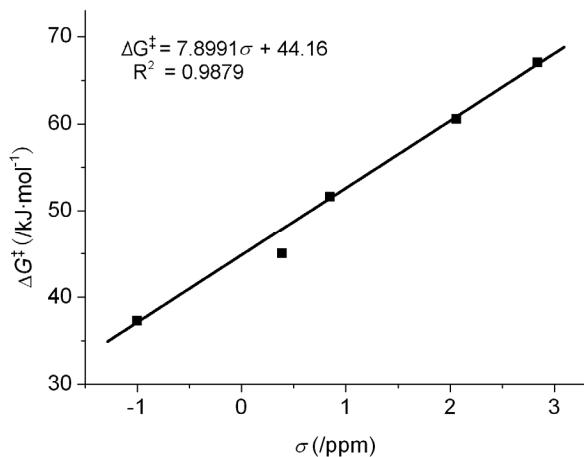

Magnification of HH COSY spectra of model compounds 4 at 228 K

## 5. Correlation analysis of $\Delta G^\ddagger$ to chemical shift of the protons in phenyl bridged and straps

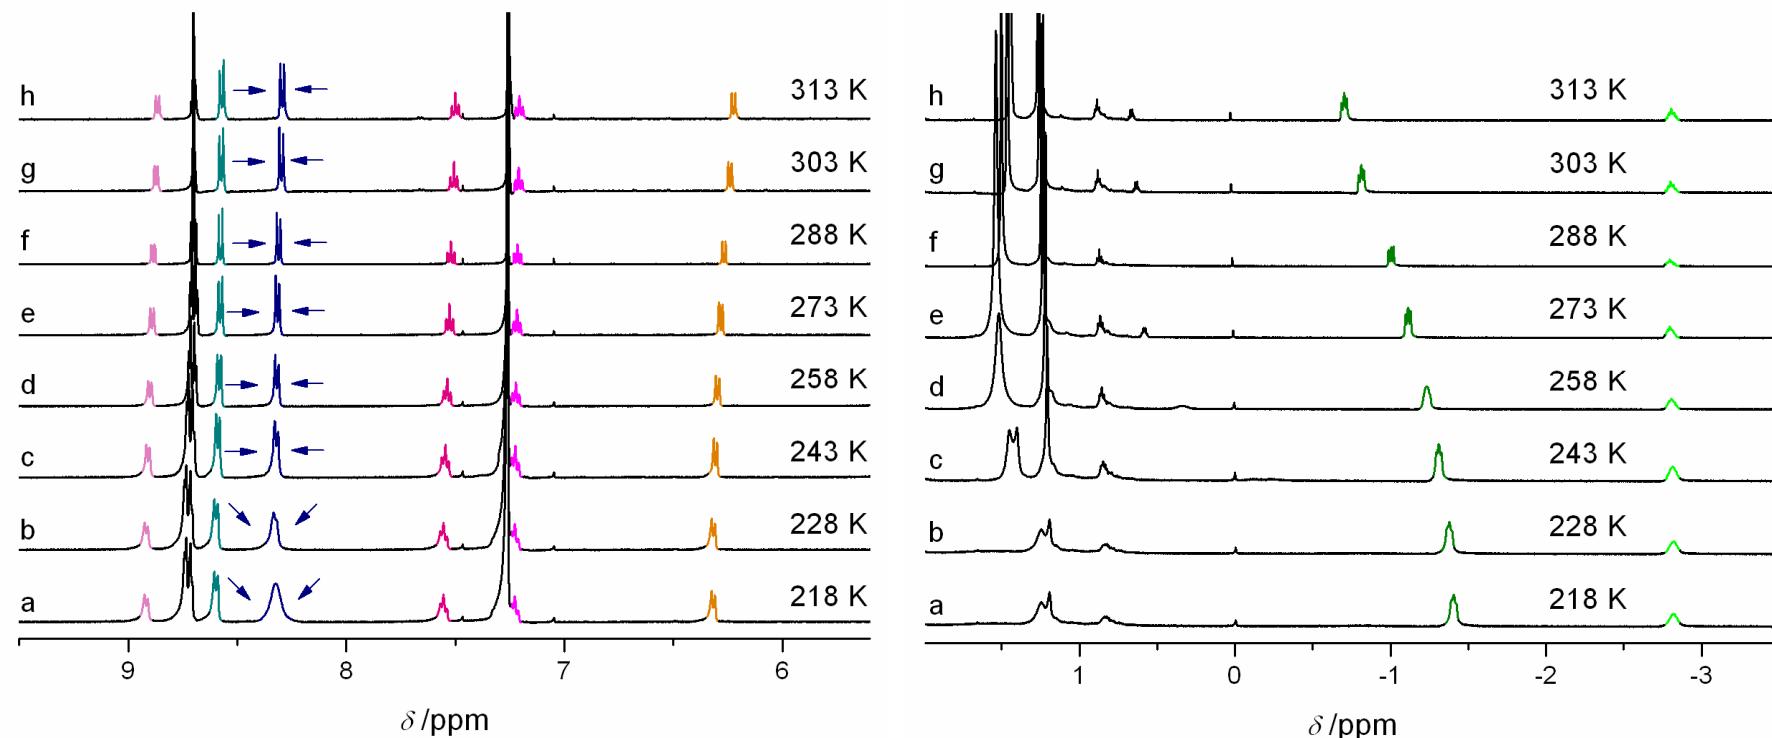

Compd.	$\Delta G^\ddagger$ (/kJ/mol)	$\delta H_1$ (/ppm)	$\delta OCH_2$ (/ppm)
1	37.3	6.24	-1.00
2	45.0	6.46	0.39
3	51.6	6.74	0.85
4	60.5	6.84	2.06
5	67.0	7.18	2.84

Correlation analysis of  $\Delta G^\ddagger$  to  $\delta OCH_2$  (left) and to  $\delta H_1$  (right). Inserts are the empirical equation

## 6. Variable-temperature $^1\text{H}$ NMR spectra of model compounds 1 to 5

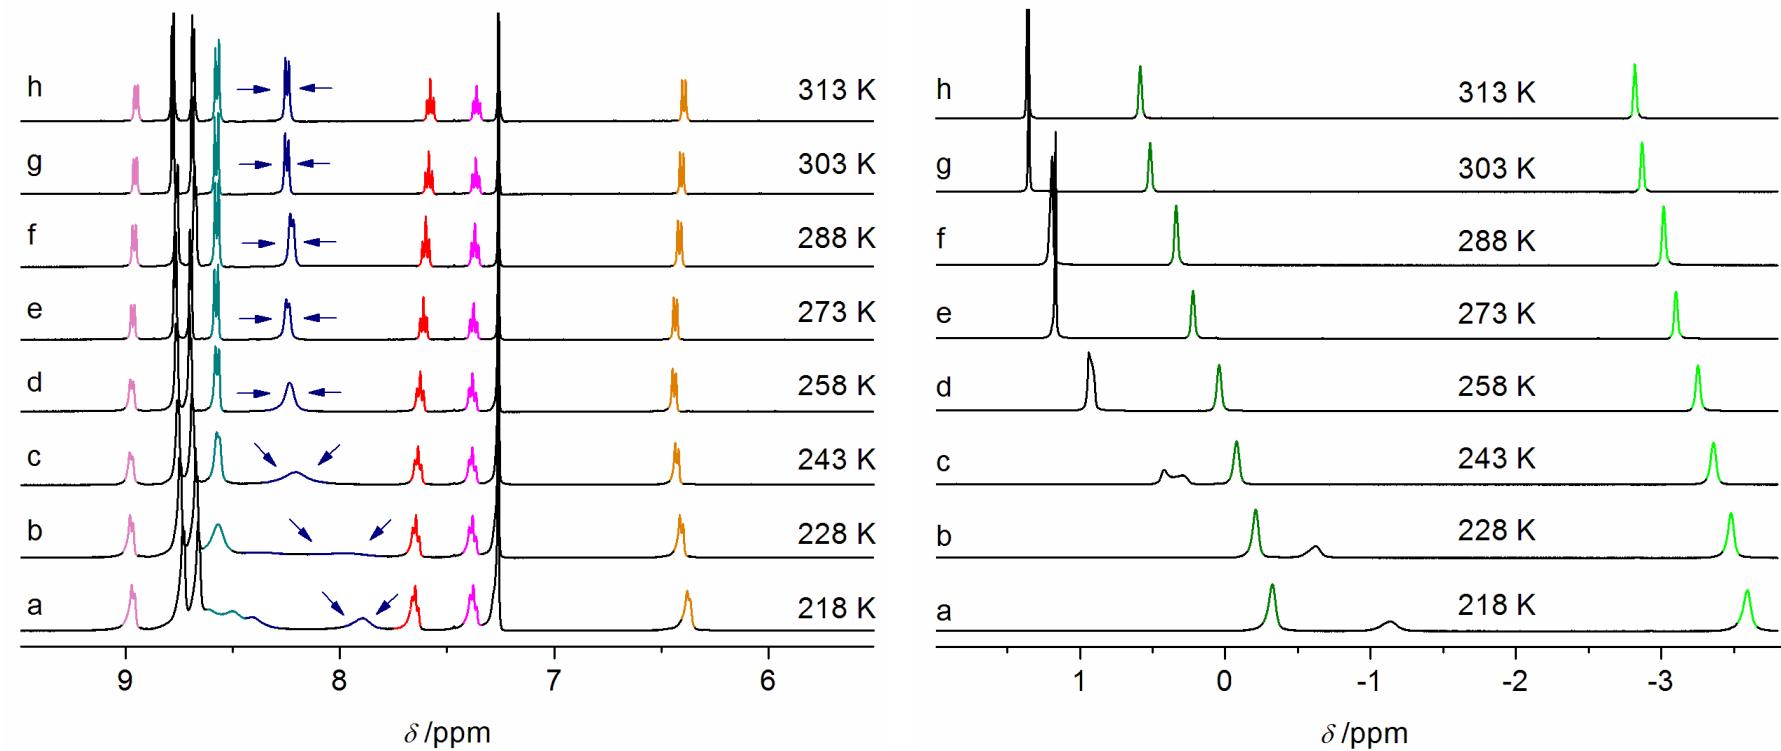

### 6.1 VT-NMR of compounds 1 ( $n_{\text{C}} = 3$ )

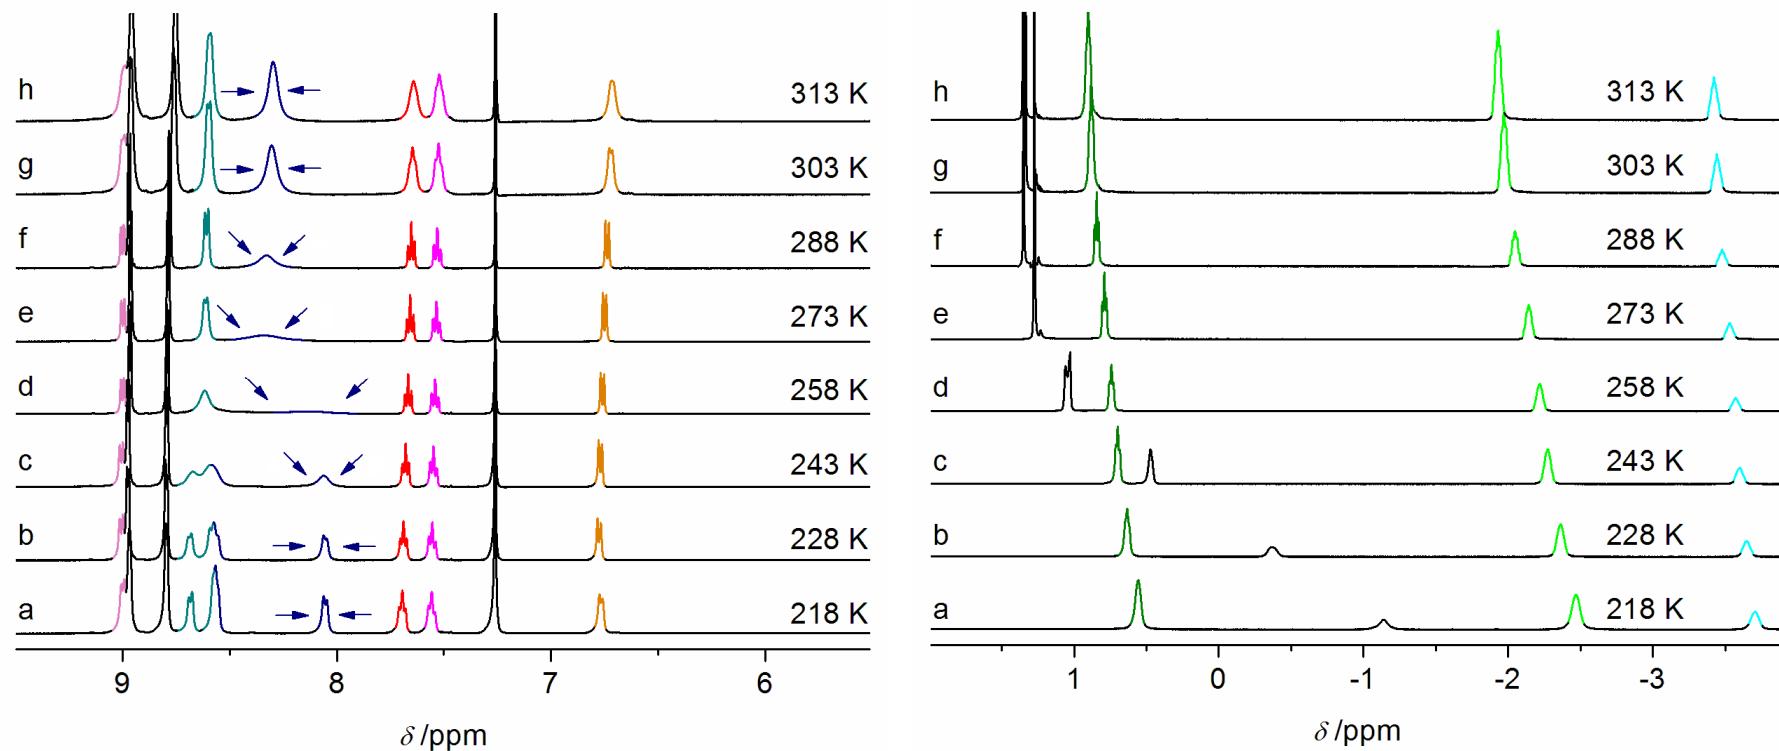

The solubility of compound 1 is very poor below 218 K, which is not convenient to acquire its exact shift value at the low temperature.

The arrows denote the half-height positions of peak diagnostic proton  $\text{H}^7$ , the same as below.

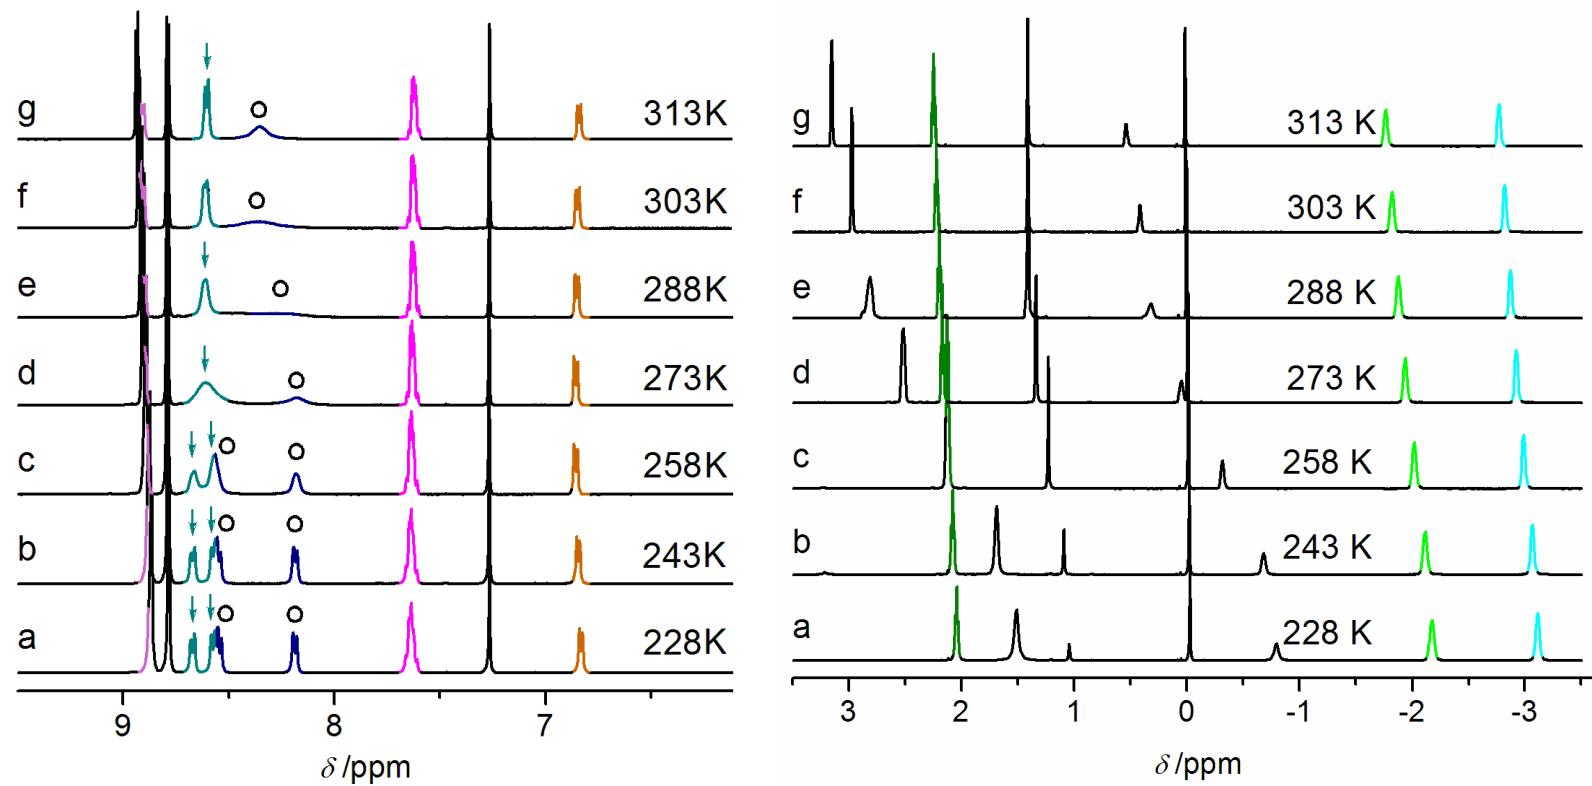

## 6.2 VT-NMR of compounds 2. ( $n_C = 4$ )

### 6.3 VT-NMR of compounds 3. ( $n_C = 5$ )

**6.4 VT-NMR of compounds 4. ( $n_C = 6$ )**

**6.5 VT-NMR of compounds 5. ( $n_C = 7$ ).**
