2. Isolation procedure

Frozen sample of a *Latrunculia* sp. (4 kg) recovered during the NOAA deep ocean surveys was cut into 2-3 cm³ pieces and extracted with ethanol (95%) with the help of an ultrasonicator at room temperature. The solvent was removed under vacuum and yielded a brownish crude extraction (225 g) which was then loaded on a flash silica gel column eluting under vacuum with a gradient elution system of hexane-ethyl acetate (50:50, 0:100) followed by ethyl acetate-methanol (75:25, 50:50, 0:100) then methanol-water (50:50). The fractions of ethyl acetate-methanol (75:25, 50:50) were combined and separated by using Sephadex LH-20 with an elution system of dichloromethane-methanol (50:50). The fractions with molecular weight range from 300-700 Daltons (monitored by using LC-MS) were further isolated by using C18 MPLC eluted with methanol-water (0.03% trifluoroacetic acid). The fractions eluted with 10-60% methanol were subjected to preparative HPLC (Phenomenex C₈ column, 21.2 × 250 mm with flow rate at 10 ml/min) using the elution system of MeCN- H₂O (0.05% trifluoroacetic acid) (9:1) to yield atkamine (5 mg) named after Atka Island. Green-purple solid as TFA salt. HRESIMS 734.3006 [M+H]⁺ and 736.3008 [M+H+2]⁺ (calcd. for C₄₀H₅₃BrN₃O₃S, Δ 2.79ppm). UV $\lambda_{\text{max}}=360\text{nm}$.

3. Olefin metathesis of atkamine

Atkamine (2 mg, 0.003 mmol) was dissolved in anhydrous dichloromethane (0.5 ml). Grubbs' catalyst generation II (2 mg) was then added in the solution, and the mixture was flushed with ethylene gas for fifteen minutes by using an ethylene balloon. The mixture was stirred at room temperature under ethylene atmosphere for overnight (approximately 12 hours). The reaction mixture was then diluted with dichloromethane and filtered. The crude mixture was analyzed by LC-MS. A peak cluster at m/z 650[M+H]⁺ and 652 [M+2]⁺ was detected by LC-MS which supported the olefinic double bond was placed between C-37 and C-38.

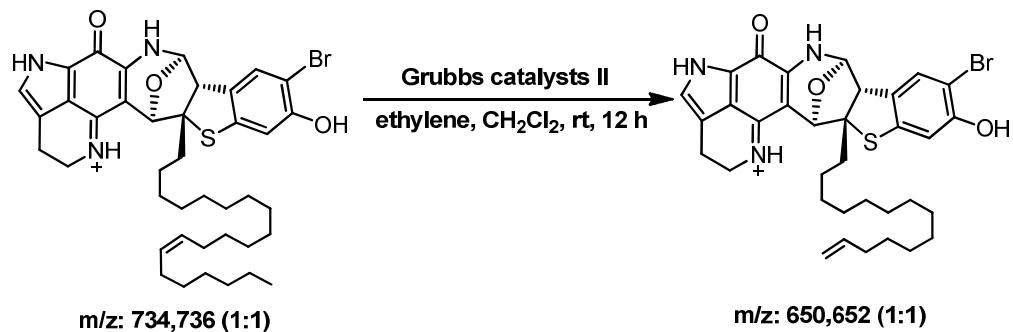

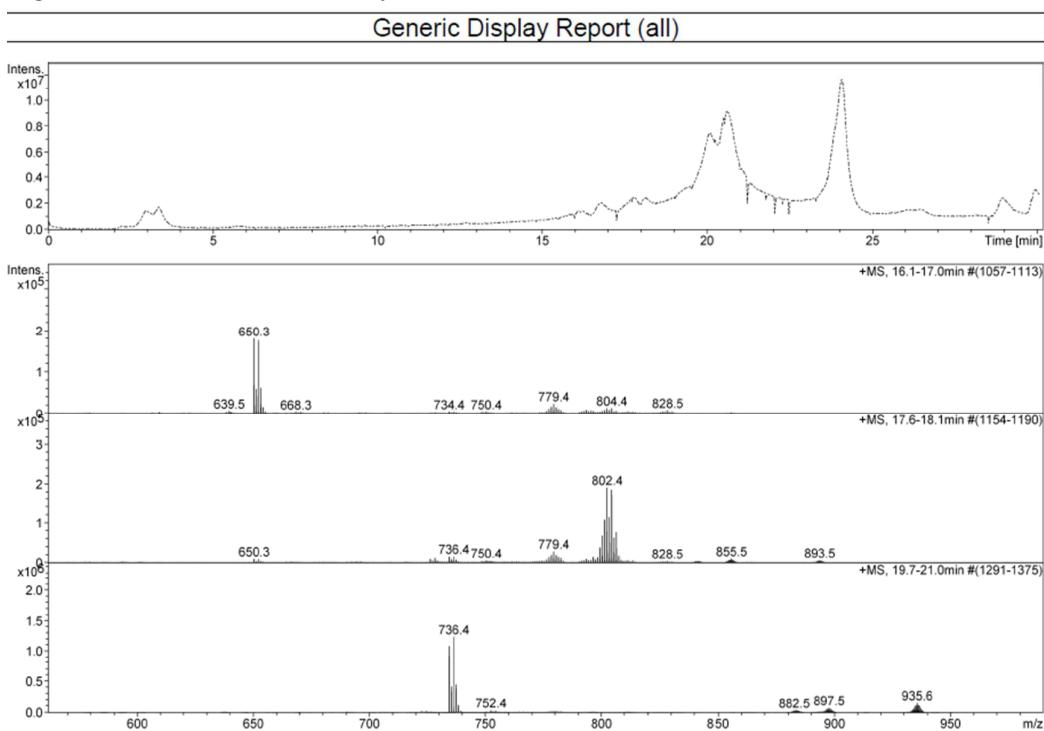

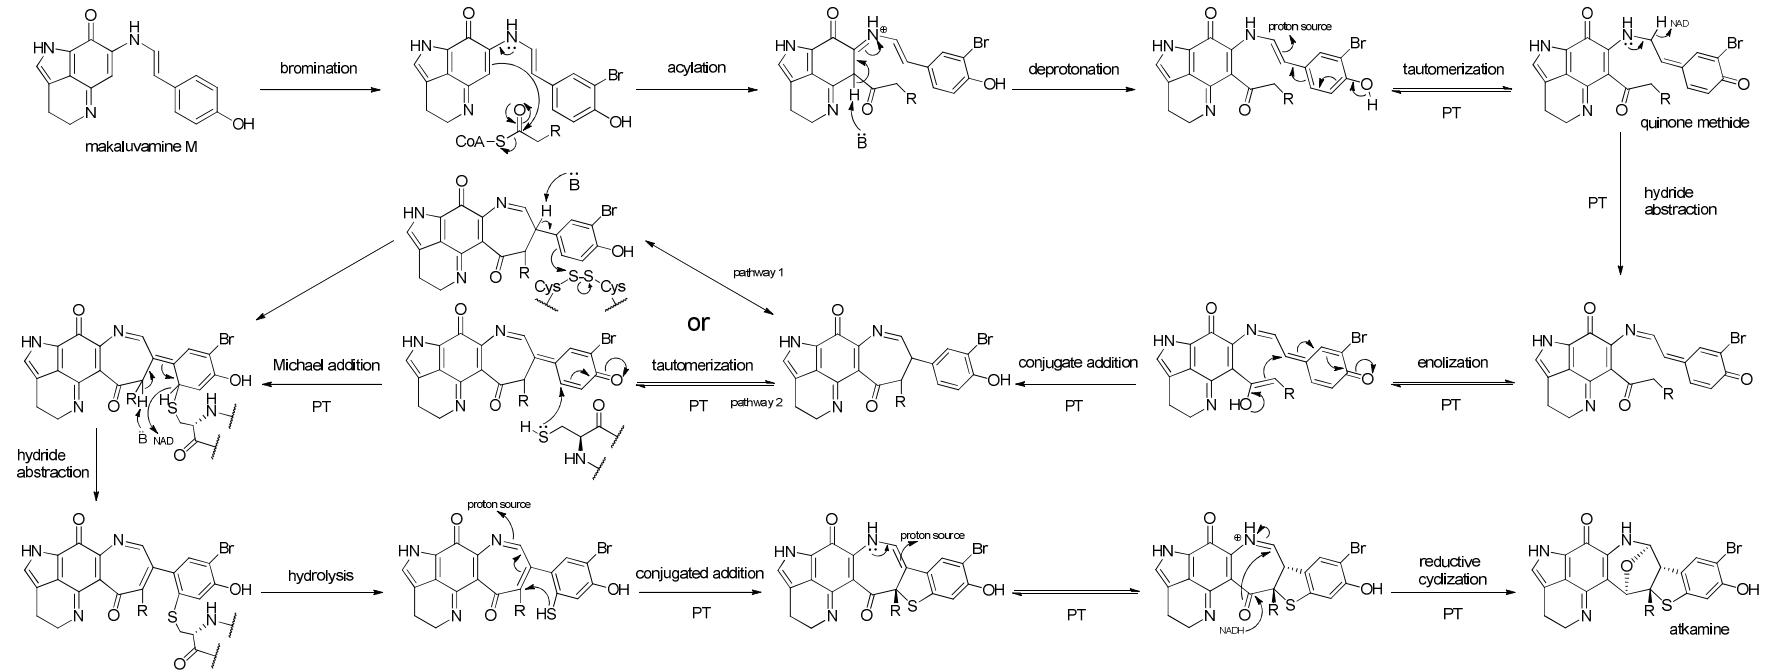

Figure S10. LC- ESI-TOF analysis of the reaction mixture.

4. Proposed biotransformation of atkamine from makaluvamine F.

A proposed biogenesis of atkamine maybe initiated by bromination¹. The following acylation is done by the nucleophilic attack of the enamine motif to the carbonyl on the VLCFAs (very long-chain fatty acids) precursor² from the unsaturated fatty acids biosynthesis pathway^{3,4}. A deprotonation of the α -position happens to regenerate the conjugation and the enamine motif. Then, the quinone methide intermediate⁵ is generated through tautomerization. NAD hydride abstraction could follow to generate the imine moiety conjugated to the pyrroloiminoquinone core. Then the acyl group is enolized to perform a conjugate addition on the quinone methide⁶ to construct the seven membered ring. The following sulfur incorporation could be via two possible pathways. The first one included a disulfide linkage serving as a sulfur electrophile, and the second pathway could be a Michael addition to the quinone methide moiety⁷ via a cysteine thiol group as a nucleophile. Both pathways lead to a dearomatized intermediate and subsequently recover the aromaticity and the conjugation by the assistance of NAD. A hydrolysis releases the free thiol which could undergo a conjugated addition to form the core ring system. The iminium moiety is then reformed from a reductive cyclization to form atkamine.

Figure S11. Proposed biogenesis of atkamine.

5. Configuration assignment of atkamine

General computation procedure.

All calculations were performed by using Gaussian 09 software package. The visualization process was performed by using the Gaussian View software and the Molekel software. The aliphatic chain part was pre-optimized to the lowest energy conformation. Conformational analysis was then conducted, and two low energy conformations were generated. Each conformation was minimized by using the MMFF method and then used for the geometry optimization and the frequency calculation by the hybrid DFT calculation with the B3LYP or BH&HLYP methods with the 6-31G(d,p) or TZVP basis set and the PCM solvation model with the dielectric constant representing methanol to generate the optimized structure and a set of thermodynamic data. This structure was then used for the excited-state TDDFT calculations to generate the excitation energies and rotational strengths as well as the electronic structures. The resulted excitation energies and rotational strengths of different conformers were Boltzmann averaged and fitted to a Gaussian function to generate the computed ECD spectrum.

Figure S12. Optimized structure of the lowest energy conformation of atkamine by using the DFT calculation with the B3LYP method and the 6-31G(d,p) basis set with the PCM solvation model.

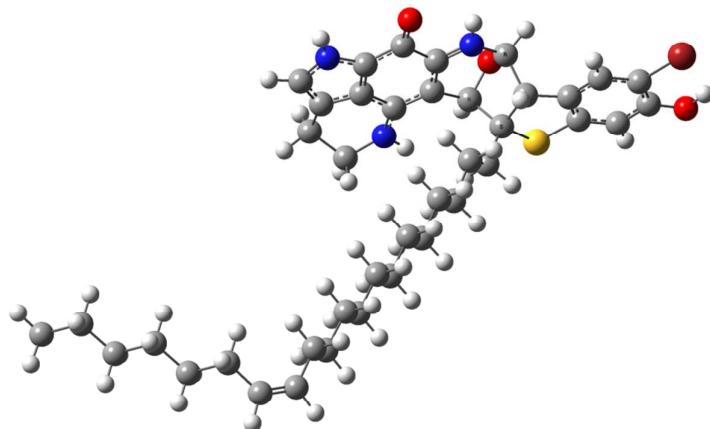

Figure S13. ESP (electrostatic potential) surface of the lowest energy conformation of atkamine by using the DFT calculation with the B3LYP method and the 6-31G(d,p) basis set with the PCM solvation model.

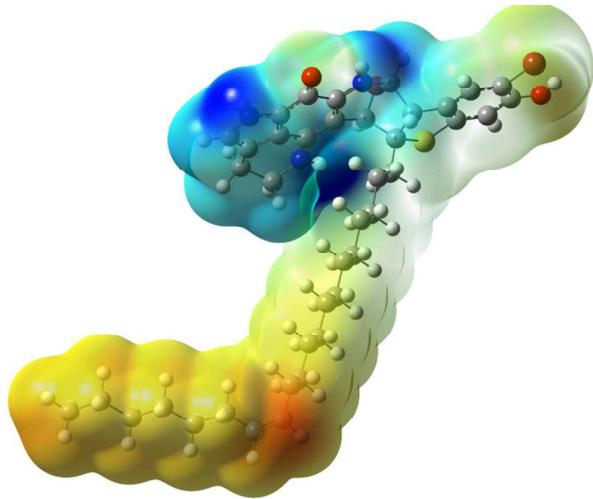

Figure S14. Calculated HOMO and LUMO of the lowest energy conformation of atkamine by using using the TDDFT calculation with the B3LYP method and the 6-31G(d,p) basis set with the PCM solvation model.
