## 1. Sample $\mathbf{N}_{\mathbf{2}}$ Adsorption-Desorption Isotherms

Figure S1. Adsorption (red) / desorption (blue) isotherms for fluid coke, 53-106 $\mu \mathrm{m}$, before activation. The desorption isotherm was not used in the calculation of physical parameters.

Figure S2. Adsorption (red) / desorption (blue) isotherms for fluid coke, 53-106 $\mu \mathrm{m}$ initial diameter, activated 5 hours at $700^{\circ} \mathrm{C}, 50 \% \mathrm{SO}_{2}$. The desorption isotherm was not used in the calculation of physical parameters, but serves as a qualitative indicator of extensive mesoporosity (as indicated by large hysteresis loop).

## 2. QSDFT Pore Size Distribution for Raw Coke

Figure S3. QSDFT pore size distribution for fluid coke, 53-106 $\mu \mathrm{m}$, before activation. This analysis used only the adsorption branch, assuming slit-shaped geometry for pores less than 1 nm radius, and cylindrical geometry for those greater than 1 nm radius. Note that the initial peak at the far left is an artefact of the limited pressure range; a more extensive micropore analysis at relative pressures down to $\sim 10^{-7}$ would provide better resolution for pores less than 0.65 nm in radius, although this would entail a much greater analysis time (up to 48 hours).

## 3. Calculation of Specific Pore Length, $L_{0}$

To obtain the total pore length for a range of pore radii, we must integrate under the pore length distribution curve $L\left(r_{P}\right)$. However, most surface analyzers provide the pore volume distribution, $V\left(r_{P}\right)$, as raw output, so we must first convert the data.

For a cylindrical pore, $V=\pi r_{P}^{2} L$, where $V$ is the pore volume, $r_{P}$ is the pore radius, and $L$ is the pore length. Rearranging to solve for $L$, we get:

$$
\begin{equation*}
L=\frac{V}{\pi r_{P}^{2}} \tag{S1}
\end{equation*}
$$

Total pore length is obtained by replacing $L$ and $V$ in Equation S 1 with their respective distribution functions and integrating with respect to $r_{P}$ :

$$
\begin{align*}
& \int_{0}^{\infty} d L\left(r_{P}\right)=\int_{0}^{\infty} \frac{V\left(r_{P}\right)}{\pi r_{P}^{2}} d r_{P}  \tag{S2}\\
& \quad \Rightarrow L=\frac{1}{\pi} \int_{0}^{\infty} \frac{V\left(r_{P}\right)}{r_{P}^{2}} d r_{P} \tag{S3}
\end{align*}
$$

In practice, it is difficult to obtain an analytical expression for $V\left(r_{P}\right)$. Therefore, the $d V\left(r_{P}\right)$ values automatically generated by the Quantachrome ASiQwin software were converted to $d L\left(r_{P}\right)$ using the relations provided above and summed using the trapezoidal rule:

$$
\begin{equation*}
\text { Area }=0.5\left(r_{P, n+1}-r_{P}\right)\left(d L_{n}+d L_{n+1}\right) \tag{S4}
\end{equation*}
$$

Where Area denotes the area under the $d L\left(r_{P}\right)$ versus $r_{P}$ curve between points $n$ and $n+1$. Table S1 provides the software output along with the derived values of $d L\left(r_{P}\right)$ and the trapezoidal area results for unreacted fluid coke, 53-106 $\mu \mathrm{m}$ diameter.

Note that the Random Pore Model requires physical pore dimensions for the unreacted solid material. Thus, in the manuscript, $V\left(r_{P}\right), V_{P}$, and $L$ are written as $V_{0}\left(r_{P}\right), V_{P 0}$, and $L_{0}$ to specify them as being initial properties.

Table S1. QSDFT output and $L_{0}$ quantification for unreacted fluid coke, 53-106 $\mu \mathrm{m}$ diameter

| Sum: |  |  |  |  | $2.20 \mathrm{E}+11$ |

The summed result, in units of $\mathrm{cm} \mathrm{g}^{-1}$, is then divided by the total pore volume, $V_{P 0}$, to obtain a value in units of $\mathrm{cm} \mathrm{cm}^{-3}$ (as required by the Random Pore Model). However, as described in Section 2.2 of the manuscript, the total pore volume was calculated using both QSDFT and BJH techniques, since QSDFT is limited to pores less than 33 nm in diameter. Table S 2 illustrates how BJH pore size data was appended to the data given in Table S1 as a means of obtaining a more accurate measure of $V_{P 0}$, i.e., $0.0112 \mathrm{~cm}^{3} \mathrm{~g}^{-1}$. This results in a final $L_{0}$ value of $2.08 \times 10^{13}$ $\mathrm{cm} \mathrm{cm}^{-3}$, as shown in Table 1 of the manuscript.

Table S2. Use of BJH data for larger pore sizes (BJH data shaded in grey)

| Pore radius, nm | Pore diameter, nm | Cumulative Pore Volume, $\mathrm{cm}^{3} \mathrm{~g}^{-1}$ |
| ---: | ---: | ---: |
|  | 0.6495 | 1.299 |
|  |  |  |

## Notes:

- The initial Area value shown in Table S1 is the result of applying the trapezoidal rule between the first data point and the origin, as shown in Figure S4. The result is a rough estimate of the pore length in the small micropore region. Future work would benefit from performing a more detailed micropore analysis, which would allow for more accurate determination of $L_{0}$.
- The quantification of $L_{0}$ was only carried out in the QSDFT range, i.e., $<33 \mathrm{~nm}$. While pores above this size may contribute to pore volume, they will have insignificant impact on overall pore length.

Figure S4. QSDFT pore volume distribution with area used for $L_{0}$ determination shaded in pink. The dashed line represents an approximation of the distribution in the small micropore range.

## 4. Instructions for Simulating Porous Layer Development

Please refer to Figure S 5 when reading the following instructions for simulating porous layer development in a fluid coke particle of $12 \mu \mathrm{~m}$ initial diameter using the spherical shell approach.

Column A: Time of activation, which, in this case, is divided into elements of 0.001 hours to enhance resolution.

Column B: $R$, the outer particle radius based on particle size measurements and following Equation 1.

Column C: $r$, the unreacted core radius based on SEM core measurements and following Equation 2. Due to the small initial particle size, the value of this column becomes 0 before a constant thickness porous layer, $\delta_{\max }$, is achieved (not shown in Figure S5). With larger particle sizes, $r$ would be set to decrease at the same rate as $R$ at the time at which $\delta_{\max }$ is reached.

Column D: $\delta$, the overall porous layer thickness, or $R-r$.
Column E: $R_{0.05}$, the outer activated radius of the first spherical shell. Since this is the first shell, its outer radius is equivalent to that of the particle, $R$. The subscript " 0.05 " refers to the depth of this shell with respect to the initial outer surface, i.e., $0.05 \mu \mathrm{~m}$. This naming system is, of course, arbitrary. Note that in Figure $\mathrm{S} 5, R_{0.05}$ is shown in units of $\mu \mathrm{m}$, whereas, in the manuscript, $R_{i}$ is defined in units of cm for the sake of consistency within the text.

Column F: $r_{0.05}$, the inner activated radius of the first spherical shell. It follows the unreacted core radius, $r$, until the point at which the shell reaches its designated thickness of (approximately) $0.05 \mu \mathrm{~m}$. After this point, $r_{0.05}$ is constant. As with $R_{0.05}, r_{0.05}$ is shown in units of $\mu \mathrm{m}$ in Figure S 5 .

Column G: $\delta_{0.05}$, the activated thickness of the first shell, or $R_{0.05}-r_{0.05}$. This initially increases due to the growing discrepancy between $R_{0.05}$ and $r_{0.05}$, until its designated thickness of (approximately) 0.05 is reached. After this point, it steadily diminishes as $R$ encroaches on the first shell. At some point (row 43, $t=0.041$ hours, in this case), $\delta_{0.05}$ diminishes to zero, which marks the point at which the other columns related to the first shell must end.

Column H: $X_{0.05}$, the fractional conversion of the first shell. The equation used to calculate $X_{i}$ is:

$$
X_{i}=\frac{t-t_{0}}{t_{f}-t_{0}}
$$

Where $t$ is the current time, $t_{0}$ is the time at which the shell initially becomes activated ( $t=0$ for the first shell), and $t_{f}$ is the time at which the shell is spent ( $t=0.041$ hours for the first shell). This produces a linear progression from 0 to 1 .

Column I: $V_{0.05}$, the activated volume of the first shell, as calculated by Equation 7 in the text. In Figure S5, $V_{0.05}$ is shown in units of $\mu \mathrm{m}^{3}$.

Column J: $M_{0.05}$, the activated mass of the first shell, as calculated by Equation 8 in the text. This value is displayed in units of grams.

Column K: $S_{0.05}$, the activated surface area of the first shell, as calculated using the Random Pore Model (Equation 3 in the text). It must be noted that, in Figure S5, $S_{i}$ was calculated in units of $\mu \mathrm{m}^{2} \mu \mathrm{~m}^{-3}$ and subsequently multiplied by $V_{i}$ (column I), so the values in column K are in units of $\mu \mathrm{m}^{2}$.

Column L: $R_{0.1}$, the outer activated radius of the second spherical shell. The starting point for this shell coincides with the point at which the previous shell reaches its designated maximum thickness, since this is the point where $r$ encroaches on the second shell $(t=0.006$ hours in Figure S5). Note that $R_{0.1}$ is equal to $r_{0.05}$ until the time at which the first shell is spent $(t=0.041$ hours), as this marks the point at which $R$ begins encroaching upon the second shell.

Column M: $r_{0.1}$, the inner activated radius of the second spherical shell. As with the first shell, $r_{0.1}$ is equivalent to $r$ until $\delta_{0.1}$ reaches a thickness of approximately $0.05 \mu \mathrm{~m}$, after which it remains constant.

Columns N, O, P, Q, and R: Analogous to columns G, H, I, J, and K.
From this point onwards, all remaining shells are constructed in the same manner until the particle has been completely consumed. Total SSA is found by summing all of the $S_{i}$ columns and dividing by the total mass, as shown in Equation 12 in the text.

Figure S 5 may be easier to understand by comparing with Figure 1 in the text. At $t=0.014$ hours, the first, second, and third spherical shells have been activated. The activated portion of the first shell is shrinking since it is no longer completely within the porous layer, similar to the $4^{\text {th }}$ shell in Figure 1. The second shell in Figure S5 is completely within the porous layer, as are the $5^{\text {th }}, 6^{\text {th }}$, and $7^{\text {th }}$ shells in Figure 1. The third shell in Figure S 5 is not yet completely within the porous layer, and is still growing, similar to the $8^{\text {th }}$ shell in Figure 1. The fourth shell in Figure S5, along with every subsequent shell, is still within the unreacted core and thus is not yet activated (i.e., it does not contribute to total SSA). At $t=0.043$ hours, the first shell in Figure S5 is no longer within the porous layer, and, as with the $1^{\text {st }}, 2^{\text {nd }}$, and $3^{\text {rd }}$ shells in Figure 1 , is no longer activated.
