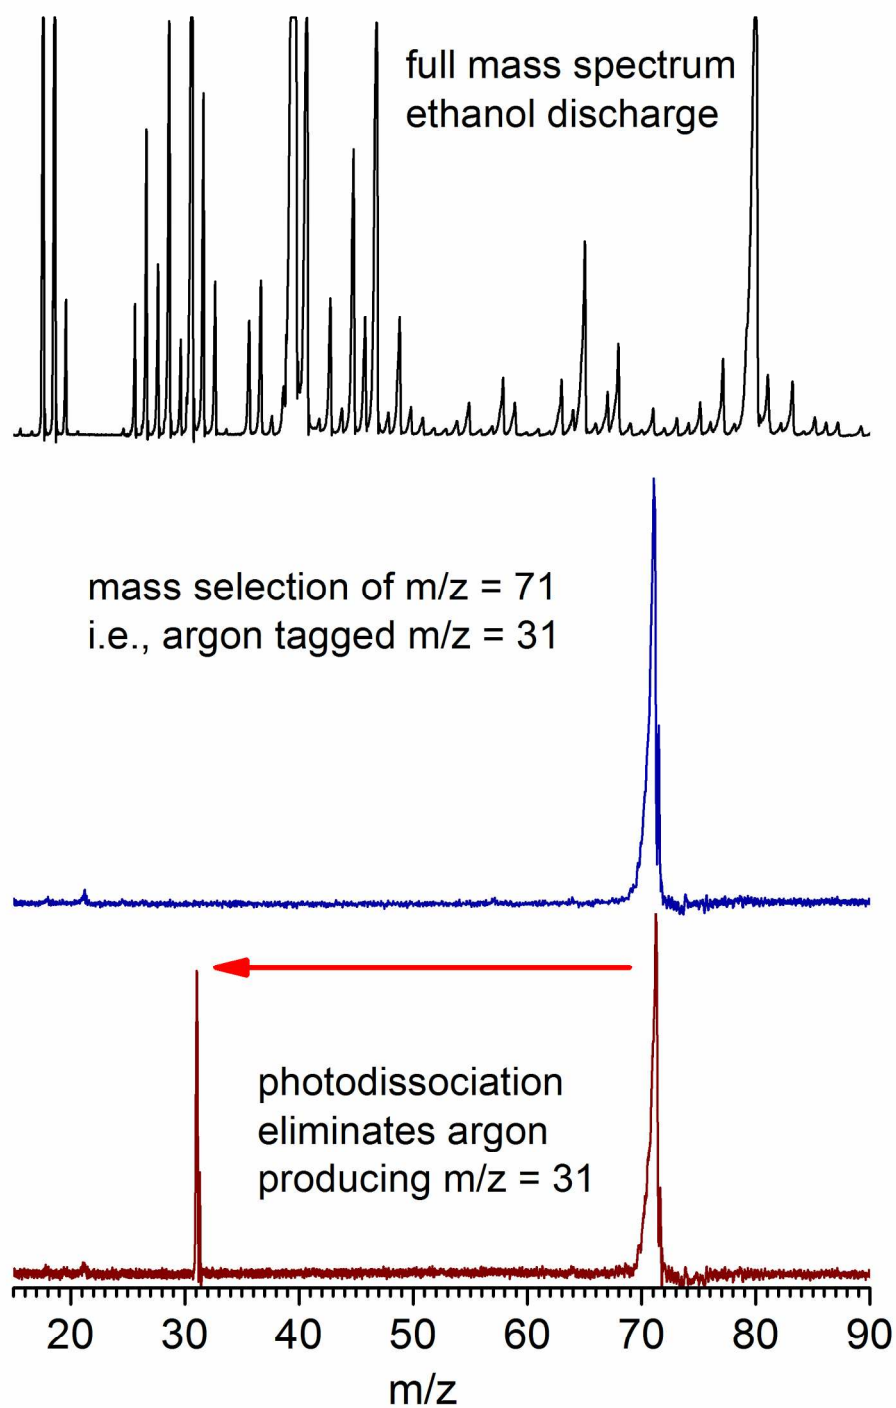

Figure S1. The mass spectrum produced from an ethanol discharge (top trace). The middle trace shows the mass-selected m/z = 71 ion corresponding to the m/z = 31 ion tagged with argon. the bottom trace shows the photodissociation of the m/z=71 ion, which proceeds by elimination of argon to produce m/z=31. This fragment ion is recorded as a function of the IR wavelength to produce a spectrum.

Table S1. Absolute and relative (to lowest energy isomer) energies of structural isomers of the mass 31 cation without argon at the RMP2 (fc) and DFT /B3LYP levels of theory. The cc-pVTZ basis set was used for all atoms. Absolute energies are in atomic units. Relative energies are in kcal/mol and are corrected for zero point energies.

Protonated Formaldehyde - Ar:
Asymmetric Top - Type A and B transition

$T_R = 25$ K

$\nu_0 = 3182$ cm^{-1}

$A'' = 1.66$ cm^{-1}

$B'' = 0.08$ cm^{-1}

$C'' = 0.08$ cm^{-1}

$T_R = 315$ K

$A' = 1.71$ cm^{-1}

$B' = 0.25$ cm^{-1}

$C' = 0.08$ cm^{-1}

cm^{-1}

Figure S20. Comparison of the observed O–H stretch of CH_2OH^+-Ar (black) at two different source conditions with simulated ro-vibrational spectra for an asymmetric top using the PGOPHER program.

Figure S21. The variation in the component of the dipole moment along the *b*-axis, plotted -as a function of the HOC(H$_2$) torsion angle (τ). The blue open circles are for the complex with argon present, while the red solid ones are for the complex without argon.

Figure S22. The variation in the component of the dipole moment along the *c*-axis, plotted -as a function of the HOC(H_2) torsion angle (τ). The blue open circles are for the complex with argon present, while the red solid ones are for the complex without argon.
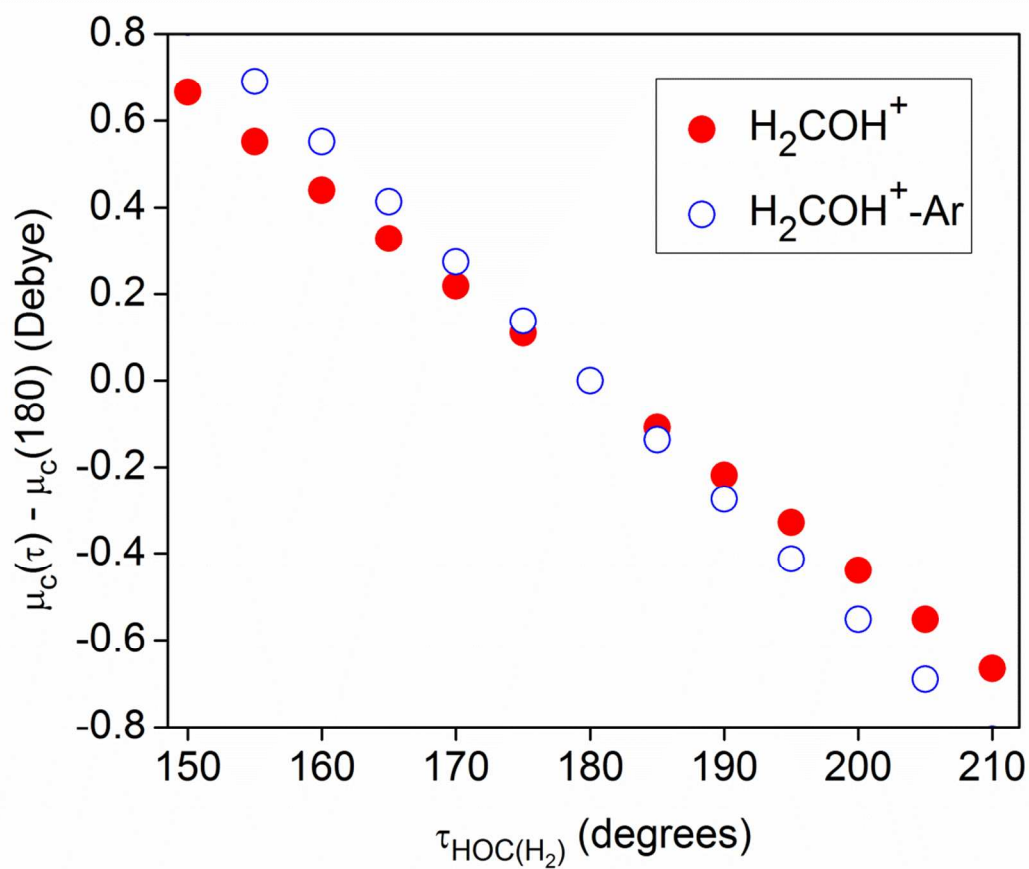

Analysis of the combination band at 3340 cm^{-1}

We follow an approach that is similar to the one taken by Myshakin et al in their analysis of complexes of $CH_3NO_2^-$ and $CH_3CO_2^-$ with H_2O [J. Chem. Phys. **2003**, *119*, 10138]. In the present analysis, the Hamiltonian is reduced to the two normal coordinates, which are treated in the harmonic approximation. The two chosen coordinates are the OH stretch (q_1) and the Ar-H stretch (q_{11}). The one anharmonic term that is included is the cubic coupling term of the form ½ $f_3 q_1^2 q_{11}$, and the value of all the constants are obtained from a calculation at the MP2/6-311++G(d,p) level of theory/basis, as implemented in Gaussian. This gives a Hamiltonian of the form

$$H = \frac{p_1^2}{2} + \frac{p_{11}^2}{2} + \frac{\omega_1^2}{2} q_1^2 + \frac{\omega_{11}^2}{2} q_{11}^2 + \frac{f_3}{2} q_1^2 q_{11}.$$

In the present analysis, the energies and wave functions are obtained by employing an adiabatic approximation in which the OH stretch is treated as the high frequency mode and the eigenvalues and eigenvectors of the Hamiltonian

$$h_1(q_{11}) = \frac{p_1^2}{2} + \left(\frac{\omega_1^2}{2} + \frac{f_3}{2} q_{11} \right) q_1^2$$

are evaluated as functions of q_{11}. This yields expressions for the energies of

$$E_{n_1}(q_{11}) = \hbar \sqrt{\omega_1^2 + f_3 q_{11}} \left(n_1 + \frac{1}{2} \right)$$

$$\approx \hbar \omega_1 \left(1 + \frac{f_3}{2\omega_1^2} q_{11} \right) \left(n_1 + \frac{1}{2} \right)$$

The above approximation is introduced to make the problem analytically solvable, but solving the problem numerically without invoking the approximation yields essentially the same results.

In the second step, we solve for the eigenvalues of h_{11}:

$$h_{11;n_1} = \frac{p_{11}^2}{2} + \frac{\omega_{11}^2}{2} q_{11}^2 + \frac{\hbar f_3}{2\omega_1} \left(n_1 + \frac{1}{2} \right) q_{11} + \hbar \omega_1 \left(n_1 + \frac{1}{2} \right)$$

$$= \frac{p_{11}^2}{2} + \frac{\omega_{11}^2}{2} \left(q_{11} + \frac{\hbar f_3}{2\omega_1 \omega_{11}^2} \left(n_1 + \frac{1}{2} \right) \right)^2 - \frac{\hbar^2 f_3^2}{8\omega_1^2 \omega_{11}^2} \left(n_1 + \frac{1}{2} \right)^2 + \hbar \omega_1 \left(n_1 + \frac{1}{2} \right)$$

which yields

$$E_{n_1,n_{11}} = \hbar \omega_1 \left(n_1 + \frac{1}{2} \right) + \hbar \omega_{11} \left(n_{11} + \frac{1}{2} \right) - \frac{\hbar^2 f_3^2}{8\omega_1^2 \omega_{11}^2} \left(n_1 + \frac{1}{2} \right)^2$$

Here the corresponding wave functions are harmonic oscillators, and they are centered around

$$q_{11}^{\min}(n_1) = -\frac{\hbar f_3}{2\omega_1\omega_{11}^2}\left(n_1 + \frac{1}{2}\right)$$

rather than $q_{11}=0$.

The overlap of shifted harmonic oscillator eigenstates are well-known, and within a Franck-Condon treatment the intensities of combination bands involving one quantum of excitation in the OH stretch and n_{11} quanta in the Ar-H stretch rae given by

$$I_{n_{11}} = \frac{e^{-\Delta q_{11}^2/2}\left(\Delta q_{11}\right)^{2n_{11}}}{2^{n_{11}}n_{11}!}$$

where (in dimensionless coordinates)

$$\Delta q_{11}(n_1) = -\frac{\hbar f_3 n_1\sqrt{\omega_{11}}}{2\omega_1\omega_{11}^2} = -\frac{\tilde{F}_3 n_1}{2\tilde{\omega}_{11}}$$

Using the values from the electronic structure calculations, $\tilde{\omega}_1 = 3503$ cm^{-1}, $\tilde{\omega}_{11} = 130.6$ cm^{-1}, and $\tilde{F}_3 = 72.79$ cm^{-1} leads to the prediction that the fundamental of the OH stretch gets 96.2% of the integrated intensity while the remaining 3.8% would go to the combination band involving one quantum in each mode.
