1 Computational Details of DFT calculations

Here we provide the detailed explanation of DFT methodology we use in this work. All calculations were performed using the DFT code Jaguar 7.7¹ with modified OpenMP/MPI hybrid parallel implementation on a 48-core workstation. Complete geometric optimization of species with up to 400 atoms can be done in several weeks. The oxygen, hydrogen and lithium atoms were treated by all-electron 6-31G basis set and the titanium was computed with LACVP basis set which uses effective core potential to represent core electrons and double- ζ basis functions for valence electrons. We employed the B3LYP hybrid functional in all calculations. The hybrid functionals, unlike the local spin density (LSD) approximation and the generalized gradient approximation (GGA), which lead to delocalization problem of unpaired electrons across several Ti sites, mix a

fraction of Hartree-Fock exchange into the exchange-correlation functional to mitigate delocalization. B3LYP hybrid functionals can give semi-quantitatively reasonable band structures, band gap energies and electron localization for TiO₂ nanoparticle, which is the goal of our study. We use restricted open-shell DFT (RODFT) method and do not consider spin-orbit coupling. Because all clusters studied in this work are with either one (doublet spin) or none (singlet spin) excess electron and have no anti-ferromagnetic effects we found that RODFT gives similar, if not completely identical, results as unrestricted DFT for absolute energies and equilibrium geometries; thus ignoring spin-symmetry breaking and using a RODFT reference function is a safe trade-off for additional 20-50% of computational speed. No symmetry is assumed for calculations in our largest clusters (explained later). No geometric constraints are imposed for all ground states, and the atoms are allowed to relax completely. For transition state (TS) searches, the atoms that are 6 Å away from the reaction center are frozen to boost the searching speed. As we will show later, because the geometrical change is located at reaction center, this constraint above has only a submillihartree effect for final results.

The continuum solvent effect was modeled by Poisson-Boltzmann continuum solvation method available in Jaguar 7.7 code. In this type of calculation, the solvated system is treated with a self-consistent reaction field method, using Jaguar's Poisson-Boltzmann solver. The process consists of Jaguar first solving the usual gas phase wave function and, from that, the electrostatic potential, and fitting that potential to a set of atomic charges. These charges are used by the Poisson-Boltzmann solver, which determines the reaction field by numerical solution of Poisson-Boltzmann equation and represents the solvent as a layer of charges at the molecular surface. These solvent point charges are then incorporated into another quantum mechanical wave function calculation. The process is repeated until self-consistency is obtained.

We also comment on the choice of initial guess of wave function. In order to converge the self-consistent total energy of a compact cluster with around 400 atoms, one needs an initial wave function that is at least qualitatively correct. Traditionally, the initial guess generators provided by Jaguar are based on atomic densities,² atomic wavefunctions³ or ligand-field theory.⁴ Although

these method are proven to be efficient in small molecules, it is very difficult, if not completely impossible, to get converged wavefunctions for large three dimensional clusters starting from those initial guess generators. To overcome this problem, we established a new initial guess generator based on fragment orbital approach (FOA). The procedure was briefly described as follows. Firstly, the whole cluster was fragmented into several slices, each of which contains around 100 atoms. Then, each slice was converged without symmetry by the traditional protocol. Finally, an initial wave function was constructed from the molecular orbitals of all slices. The detailed implementation requires consideration of spin states and rotational symmetry, which will be described elsewhere. This FOA systematically improved the quality of the initial guess, which can then be fairly easily converged with the DIIS method.⁵

Finally, we want to point out that, as the system is compact as well as tremendously large, several cutoff and step size keywords must be carefully chosen. One important is `cut20`, which is the eigenvalue cutoff and decides the number of canonical orbitals kept in an SCF calculation. A tighter cutoff (2×10^{-3}) must be used instead of the default one (5×10^{-3}) in order to prevent resulting incorrect nonphysical MOs. Another important tuning was related to geometrical convergence. By default, a fixed step size algorithm is used for geometrical optimization, however, this method, especially when used with the Poisson-Boltzmann solver, usually resulted in large energetic fluctuation in magnitude of tens of millihartrees and no convergence for our model clusters after even one hundred optimization steps. A workable solution is to use the dynamic step size algorithm based on Culot/Fletcher heuristic⁶ (i.e. `itradj=1`) with carefully chosen minimum step size `tradmn=0.07`. Based on our test, for most our clusters, this approach can converge the geometry within 30-60 steps.

2 Figures of Bond Length Changes

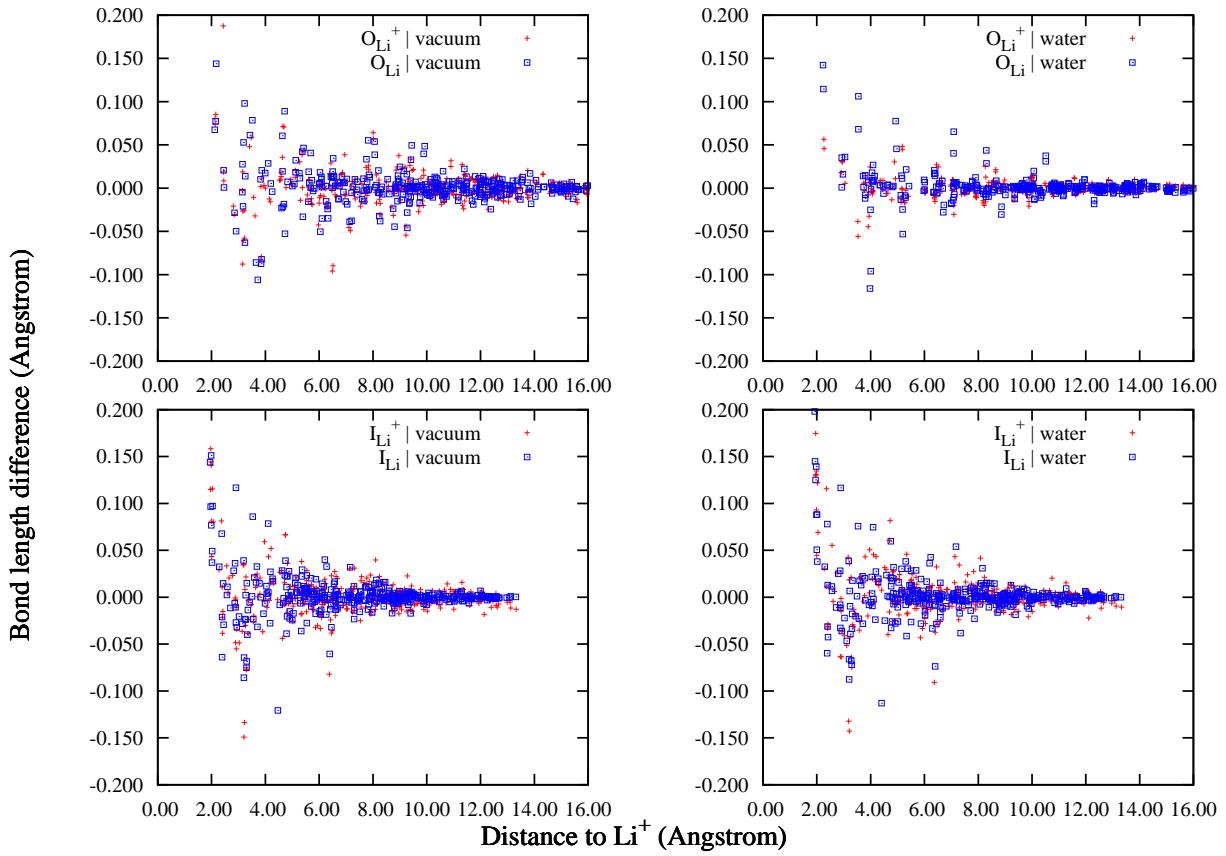

Figure S1: Bond length change of Ti-O bond in different clusters comparing to that in pure neutral TiO_2 cluster, as a function of its distance to Li^+ .

3.13.3 555 cluster

The geometry is identical to that of 555 reduced cluster in water.

4 Summary of absolute energies

Table S1: Summary of absolute energies for all 555 clusters

cluster	Li ⁺	e ⁻	sol	SCFE *
				[hartree]
(5,5,5)	/	NO	v	-17166.83035
(5,5,5)	/	YES	v	-17166.93832
