General remarks: All reactions were carried out in a flame dried flask. Solvents used for reactions and column chromatography were commercial grade and distilled prior to use. Toluene and THF were dried over sodium/benzophenone, whereas CH₂Cl₂ and CHCl₃ were dried over CaH₂. Solvents for HPLC analysis were bought as analytical grade and used without further purification. TLC was performed on pre-coated Merck silica gel aluminium plates with 60_F254 indicator, visualised by irradiation with UV light. Column chromatography was performed using silica gel Merck 60-100 mesh. ¹H-NMR and ¹³C-NMR were recorded on a Bruker AV 500 MHz using DMSO-d₆ or CDCl₃ as solvent and multiplicity indicated as follows: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), dd (doublet of doublet), dt (doublet of triplet) bs (broad singlet). Coupling constants J are reported in Hz. High resolution mass spectra were obtained by ESI using Waters/Micromass Q-TOF mass spectrometer. IR spectra were recorded on a Perkin Elmer FT/IR-420 spectrometer and are reported in terms of frequency of absorption (cm⁻¹). X-ray analysis of compound **4b** was recorded on Bruker-AXS (Kappa Apex2). The structure was solved by direct method (SHELXS-97) and refined by full-matrix least squares techniques against F2 (SHELXL-97). The enantiomeric excesses were obtained by HPLC analysis on a chiral stationary phase column (CHIRALPAK AD-H; AS-H, and CHIRAL CEL OD-H) Optical rotation was recorded on a Jasco DIP polarimeter at a wavelength of 589 nm.

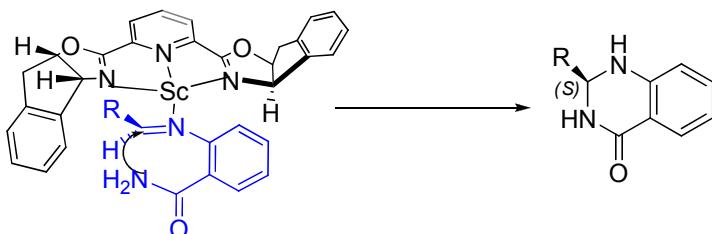

General procedure for the enantioselective synthesis of 2,3-dihydroquinazolinones.

In a oven dried flask pybox ligand **11** (7.5 μmol) and Sc(OTf)₃ (3 μmol) were taken in 1 mL of anhydrous dichloromethane. 40mg of 4Å molecular sieves was added to the solution and the resulting mixture was stirred further. After 3 h, Anthranilamide (300 μmol) solubilized in 1 mL of dichloromethane was added at the indicated temperature, followed by aldehyde (360 μmol) and stirred further at the same temperature for 4-36h. Completion of the reaction was ascertained by TLC, and the product was purified by using a small pad of silica gel 60-100 mesh to afford dihydroquinazolinones as colourless solids.

STEREOCHEMICAL OUTCOME

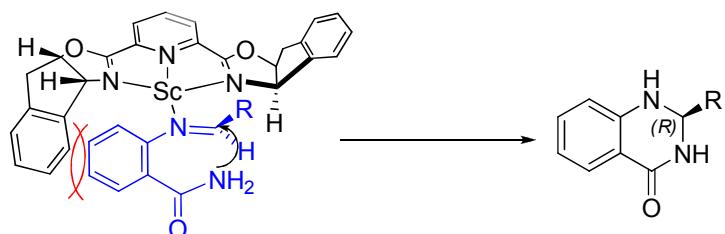

It would be difficult to predict the coordination site of monodentate imines with the Sc(III)-*inda*-pybox complexes to synthesize 2,3-dihydroquinazolinones through intramolecular amidation of imines. It is not possible without exploring mechanistic pathways. Hence we restricted ourselves to postulate herewith the approach of the substrates i.e imines to the metal complex to explain the stereochemical outcome of the product. A plausible mechanism for the stereochemical outcome of the product can be explained by a model proposed by Evans *et al.*¹ Intramolecular amidation of imines may proceed through more favoured *Si* face attack rather than unfavoured *Re* face attack since less steric hindrance is expected in the approach of reactant with the metal complex in *Si* face, which results in the formation *S*-stereoisomer (figure 2). Further mechanistic studies are currently being investigated in our laboratory.

Figure 2. A plausible mechanistic pathway

Si-face approach; less sterically hindered and more favoured

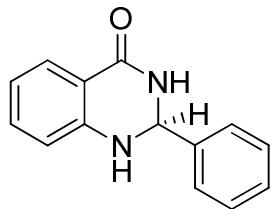

Co-ordinating triflate anions are not shown for clarity purposes

Re-face approach; more sterically hindered and less favoured
