## Synthesis procedure:

The MOFs were synthesized using the mixture of metal chlorides $\left(\mathrm{AlCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}, 99 \% ; \mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right.$, $\left.96 \% ; \mathrm{VCl}_{3}, 97 \%\right)$, terephthalic acid (TPA or $\left.\mathrm{H}_{2} \mathrm{BDC}, \mathrm{C}_{6} \mathrm{H}_{4}-1,4-\left(\mathrm{CO}_{2} \mathrm{H}\right)_{2}, 98 \%\right)$ and deionized water with the molar ratio of $1 \mathrm{MeCl}_{3}: 0.5 \mathrm{TPA}: 80 \mathrm{H}_{2} \mathrm{O}(\mathrm{Me}=\mathrm{Al}, \mathrm{Cr}$ or V$)$. All chlorides and TPA were purchased from Sigma-Aldrich and were used without further purification. The reaction mixtures containing TPA, metal chlorides and water were stirred for 5 min . The AlPOs were synthesized similarly from phosphoric acid (85 \%), pseudoboehmite ( $74.2 \%$, Catapal A, Vista Chemical Co.) and templates (triethyl amine (TEA) for AlPO-5 and di-n-propyl amine (DPA) for AlPO-11). The reactant compositions were $\mathrm{Al}_{2} \mathrm{O}_{3}: 1.0 \mathrm{P}_{2} \mathrm{O}_{5}: 1.5 \mathrm{TEA}: 100 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}: 1.0 \mathrm{P}_{2} \mathrm{O}_{5}: 1.5 \mathrm{DPA}: 100 \mathrm{H}_{2} \mathrm{O}$ for AlPO-5 and AlPO-11, respectively. The resulting reactant mixture ( 30 g ) was loaded into a Teflon-lined autoclave, sealed and placed in a preheated electric oven or in a microwave oven (MARS-5, CEM, USA, maximum power of 1200 W ) for a fixed time. The temperature of the reactant mixture was increased rapidly up to the reaction temperature in about 1.5 min and 1 h for the MW and CE syntheses, respectively. The reaction temperature was relatively low ( $125-185^{\circ} \mathrm{C}$ for MOFs and $130-150{ }^{\circ} \mathrm{C}$ for AlPOs) in order to compare the kinetics precisely to take advantage of low reaction rates at low temperature. The measured temperature was regarded as the actual reaction temperature of the system to calculate thermodynamic parameters even though the instantaneous temperature may be different to the bulk temperature. ${ }^{1}$ The dimensions of the MW and CE reactors were nearly same each other (ID: 33-35 mm , height: $110-115 \mathrm{~mm}$ ), and wide CE reactors were also used to check the effect of reactor dimension on the CE syntheses. After completion of the reactions for a predetermined time, the produced porous materials were collected by cooling (in air, natural cooling), centrifugation, washing with water and drying for 12 hours at $110^{\circ} \mathrm{C}$.

In the synthesis using microwave heating, the reaction temperature was controlled/measured using EST-300 Plus system (Electronic Sensor - Temperature) that monitored and controlled temperature conditions inside sample vessels. In this system, a microwave transparent fiberoptic temperature probe was inserted into a thermowell of a sample vessel. The temperature sensor was a phosphor located at the
tip of the probe. The decay rate of fluorescent light emitted from the phosphor is temperature dependent, allowing a precise determination of temperature. For safety, the temperature of the reaction vessel in the microwave oven was measured using an optional TempGuard ${ }^{\mathrm{TM}}$ system. An infrared lens and sensor were located in the microwave oven and the temperature of each vessel was measured as the vessels rotated over the sensor. If the temperature in any vessel was higher than the maximum pre-set temperature, the TempGuard ${ }^{\mathrm{TM}}$ stopped microwave generation.

The nitrogen adsorption was carried out using Micromeritics Tristar II 3020 surface area and porosity analyzer at liquid nitrogen temperature $\left(-196^{\circ} \mathrm{C}\right)$ after evacuation at $150^{\circ} \mathrm{C}$ for 15 h . Surface area and micropore volume were calculated with the BET equation and t-plot, respectively, using the nitrogen adsorption isotherms.

## Calculation procedure for relative crystallinity:

After synthesis of the porous materials, the materials were analyzed with XRD. The XRD crystallinity of the materials were calculated by the relative intensity of a specific diffraction peak of as-synthesized materials, compared with the fully crystallized samples under a selected condition. The ( $\left.\begin{array}{lll}2 & 0 & 0\end{array}\right)$ (2theta=about 10.3), (100) (2theta=about 7.5) and ( 0002 ) (2theta=about 21.0) diffraction peaks of MOFs, AlPO-5 and AlPO-11 were used to calculate the XRD intensity. The XRD intensity increases and saturates at a certain time, and this plateau was regarded as $100 \%$ crystallinity of the materials at the specific synthesis conditions. The XRD intensity may be changed with heating methods (such as CE and MW because of crystal size), temperatures and crystal structures (MOFs and AlPOs); however, the saturated intensity at the specific condition was used as pure crystalline materials at that condition for various reaction times. The XRD crystallinity was also evaluated after purification to remove organics in the pore structures and with 3 major XRD diffractions; however, there is little change in the crystallization curves. The syntheses were carried out for various times (at least 8 points) to derive smooth crystallization curves.

Supporting Table S1. Reaction conditions and textural properties of fully crystallized porous materials
