IR spectra

Raman spectra

---

[1] Raman spectroscopy measurements were performed on a LabRAM Aramis IR[2] spectrometer from Horiba Jobin Yvon using a red HeNe laser beam (λ = 633 nm). Spectra were recorded between 50 and 4000 cm^{-1} wavenumbers by accumulating 1 to 5 scans during 1 to 60 s per scan depending on the eventual fluorescence of the sample.

Figure S2. Rietveld plot for the refinement of the structure of Ca(PhB(OH)₃)₂.

In blue the observed diffractogram, in red the calculated diffractogram and in grey the difference plot. The peak at 2θ = 3.928° is due to the kapton foil in the beampipe.

Attempts to refine the XRD powder pattern without taking into account the most intense peak at small angles did not lead to better results. Different preferential orientation models were also tested.

Below, a zoom of the higher 2θ region of the diffractograms and difference plot above is given.

The SEM, XRD and ^{11}B solid state NMR analyses presented here were carried out in the same conditions as in the experimental section in the main text.
Ca K-edge XANES (X-ray Absorption Near Edge Structure) measurements were performed on the LUCIA beamline[2] at the Soleil Synchrotron (Saint-Aubin, France). The Soleil ring energy was 2.75 GeV and the current was 400 mA. XANES analyses were performed on Ca(PhB(OH)$_3$)$_2$ samples synthesized at room temperature and under reflux. Both samples were ground to a fine powder, diluted in polyvinyl pyrrolidone (average molecular weight 40,000, Sigma-Aldrich, "PVP40"), pressed into pellets, and run at room temperature in transmission mode. Spectra were collected at the Ca K-edge at 4038 eV. The X-ray incident energy on the sample was defined using a double-crystal Si(111) monochromator. The instrument was evacuated to ~1 Pa. An energy resolution of ~0.5 eV at the Ca K-edge was achieved and the energy was calibrated with a Ti foil (by setting the maximum of the 1st derivative at 4966 eV). The pre-edge (3950–4017 eV), edge (4017.2–4080 eV) and post-edge (4081–4200 eV) regions were scanned in 5.0, 0.2 and 1.0 eV steps respectively, with dwell times per point of 2.0 s. Data reduction was performed using the Athena software package.[3] Typically, three XANES data sets were collected for each sample, which were averaged and normalised with Athena.

Figure S6. Structural representation of Ba(PhB(OH)₃)₂, resulting from preliminary refinement tests.

Ba, B, C, H, and O atoms are represented in green, brown, grey, white and red, respectively. The H atoms of the phenyls were positioned geometrically, whereas those of the OH groups were not positioned.

Figure S7. Experimental ^{11}B MAS NMR spectra of Ca(PhB(OH)$_3$)$_2$ recorded at 9.4 T and 14.1 T, and their simulation.

Experimental ^{11}B MAS NMR spectra of Ca(PhB(OH)$_3$)$_2$, recorded on 400 and 600 MHz NMR spectrometers (in blue), together with their simulation at both magnetic fields considering the presence of 2 boron sites, and using the "best" set of NMR parameters.[4]

Simulations performed using the following ^{11}B NMR parameters

Site 1: δ_{iso} = 3.8 ± 0.3 ppm, C_Q = 1.4 ± 0.2 MHz, η = 0.4 ± 0.2

Site 2: δ_{iso} = 4.0 ± 0.2 ppm, C_Q = 1.3 ± 0.1 MHz, η = 0.2 ± 0.1

---

[4] The DMFit software was used for the NMR simulations (Massiot, D. et al. *Magn. Reson. Chem.* **2002** *40*,70).

---

[5] It is noteworthy that for the strontium structure, the discrepancy between experimental and calculated data is stronger than for the calcium one (Figure 5 in main text). This could be due to the higher difficulty in positioning H atoms in the Sr structure and/or to some mobility of the OH groups within this sample (as this can affect the overall aspect of solid state NMR spectra).

Figure S9. Representation of the inter-chain H bonds in the best DFT model of Sr(PhB(OH)₃)₂.H₂O.

The strongest H-bonds involve the water ligand. They are represented in dotted blue lines (with the water protons in blue).[6]

The other moderate H bonds mentioned in the main text involve the boronate hydroxyls. They are shown in dashed orange lines (with the corresponding hydroxyl protons in orange).[7]

The aromatic protons have been removed for clarity.

The B, C, Sr, O, and remaining H atoms are in brown, grey, green, red and white, respectively.

---

[6] The two strongest H bonds involve the water ligand, as attested from the following geometrical parameters: (O)H…O distances ~1.75 Å, O(H)…O distances ~2.75 Å, and (OHO) angles ~174°; they can be considered as "moderate" to "strong" H bonds.

[7] The two more "moderate" H bonds have the following average geometrical characteristics: (O)H…O distances ~2.0 Å, O(H)…O distances ~2.98 Å, and (OHO) angles ~170°.

Figure S10. 2D ^{1}H-^{1}H NOESY NMR spectrum of Ba(PhB(OH)$_3$)$_2$.

The 2D ^{1}H-^{1}H NOESY spectrum of Ba(PhB(OH)$_3$)$_2$ was recorded on a Bruker Avance III 700 MHz (16.45 T) spectrometer at a frequency of 700.13 MHz, using a 1.3 mm Bruker HX MAS probe spinning at 65 kHz. A 90° pulse of 1.6 μs was used, and recycle delay of 24 s. The mixing time was of 5 ms. For each spectrum, 16 transients were acquired for each of the 200 t_1 increments. The total experimental time was 21 hours.

The 1D ^{1}H NMR projections shown on the figure above correspond to the ^{1}H MAS NMR spectrum of Ba(PhB(OH)$_3$)$_2$.

This experiment shows that the protons corresponding to ^{1}H NMR signals centered at 3.0 and 2.0 ppm are close to each other within the structure, whereas the others are more distant. Such information could be valuable in the future to propose good models for this structure (i.e. models in which the protons have been properly placed), provided that better X-ray diffraction data were available.

Table S1. Fractional coordinates of the atoms of Ca(PhB(OH)$_3$)$_2$ after relaxation of all atomic positions (model M1). The lattice parameters were not relaxed.
