## **Supplementary Information.**

**PAM Syntheses.** A system of nomenclature is introduced which has its base in the nature of the RAFT agent and monomers used. The block co-polymer was assigned the letter P (from 2-{{(dodecylsulfanyl)carbonothioyl}sulfanyl}propanoic acid or DoPATTc). Beyond that a number was used to denote the number of hydrophobic monomer units (in this case zero) and hydrophilic monomer units used in the polymerisation. Thus the synthesised polymer was denoted as P0-AM7, “AM” indicating the number of acrylamide units [11]. The product, bright yellow flakes,  $T_g$  43 °C (by differential scanning calorimetry), was characterized by  $^1H$  and  $^{13}C$  spectra on a Varian 300 FT-NMR. Progress of the RAFT polymerisation was monitored by  $^1H$  NMR, using  $CDCl_3/d_6-DMSO$  as solvent. Gel Permeation Chromatography (GPC) was conducted using a Waters Breeze System operating a Waters 1515 Isocratic pump, column oven (35 °C) and Waters 2414 Refractive Index Detector.

### **Emulsion constituents**

**Table 1.** Component amounts used for the SANS emulsion experiments performed on LOQ. Errors associated with the balance are  $\pm 1 \times 10^{-4}$  g, but we have rounded the weights up to the point where, generally, differences between emulsions we wish to compare are 0.5 of the last significant digit quoted. That is, a weight of 0.30 g. has a variability between emulsions of 0.005 g.

### **Emulsion rheology**

**Table 2.** Shear stress as a function of applied shear for all emulsions. '\*' indicates shear rates with a detectable change in the incoherent scattering background along with anomalously low viscosities which we have attributed to the loss of sample in the beam path. 'N/A' indicates emulsions' that failed to form.
