Supplementary Information

Nanoarray-based Biomolecular Detection Using Individual Au-Nanoparticles with

Minimized LSPR Variations

Longhua Guo, Abdul Rahim Ferhan, Kijoon Lee and Dong-Hwan Kim * School of Chemical and Biomedical Engineering, Nanyang Technological University 637457, Singapore

Contents:

- SI 1 (Page 2): Schematic diagram of the darkfield system (Figure S1)
- SI 2 (Page 3): Spectral resolution of the system. Typical AuNR spectra obtained by different grating (Figure S2); spectral reproducibility for single AuNR detection (Figure S3)
- SI 3 (Page 4): TEM and SEM of Au nanorods, triangular Au nanoplates and truncated Au nanooctahedrons used in this work (Figure S5).
- SI 4 (Page 5): LSPR response for trangular Au nanoplates and truncated Au nanooctahedrons before and after normalization (Table S1).
- SI 5 (Page 6): LSPR wavelength shifts and corresponding normalized response for 30 individual nanoparticles (Table S2).

Supplementary Information 1:

Figure S1: Schematic diagram of the darkfield system (a) and the homemade flow cell (b).

Supplementary Information 2: Spectral resolution of the system

The imaging spectrograph employed two gratings of 300 lines/mm and 1200 lines/mm with spectral resolutions of ~0.945 and ~0.162 nm, respectively (calculated based on our PIXIS 100F CCD camera and a central wavelength of 750 nm). Although superior resolution (almost one order of magnitude better) could be obtained by using the 1200 lines/mm grating, the wavelength coverage using this grating was only 87 nm as opposed to 506 nm for the 300 lines/mm grating (Figure S2). Considering the broad peak-wavelength distributions resulting from polydispersion of the synthesized nanoparticles (Figure 3b), it was necessary to pre-scan the user-defined area with the 300 lines/mm grating to choose a suitable central wavelength for the 1200 lines/mm grating. In addition, higher line number gratings (e.g., 2400 lines/mm) could further improve the spectral resolution, which was useful for LSPR-shift measurements. However, because the typical full width at half-maximum (FWHM) of a single AuNR was ~30-60 nm, gratings with line numbers higher than 1200 are not recommended. In order to explore the reproducibility of the system for single AuNR detection, 15 replicates of the same AuNR were collected on the two gratings (Figure S3). The resulting standard deviation (σ) of the peak wavelengths was 0.22 nm for the 1200 lines/mm grating, and 1.02 nm for the 300 lines/mm grating.

Figure S2: Typical AuNR scattering spectra obtained from the two gratings.

Figure S3: LSPR scattering spectra of an AuNR obtained on 300 and 1200 lines/mm gratings. Three of the 15 spectra obtained for the same Au-nanorod are shown.

Supplementary Information 3:

Figure S4: TEM (a) and SEM (b) of AuNRs used in this work.

Figure S5 SEM of triangular Au nanoplates used in this work.

Figure S5 SEM of truncated Au nanooctahedrons used in this work.

Table S1 LSPR responses for triangular Au nanoplates and truncated Au nanooctahedrons before and after normalization*

* $\lambda_{max(1)}$: LSPR peak wavelength of AuNPs in water. $\lambda_{max(2)}$: LSPR peak wavelength of AuNPs in ethanol.

 $\Delta \lambda_{max}$: $\lambda_{max(2)} - \lambda_{max(1)}$. ΔN : LSPR responses normalized according to equation (2).

Table S2: LSPR wavelength shifts and corresponding normalized responses for the 30 particles shown in Figure 4*

 $\lambda_{max(1)}$: LSPR peak wavelength before thrombin binding. $\lambda_{max(2)}$: LSPR peak wavelength after thrombin binding.

 $\Delta \lambda_{max}$: $\lambda_{max(2)} - \lambda_{max(1)}$. ΔN : LSPR responses normalized according to equation (2).
