## XAS analysis.

All XAS spectra were analyzed using SixPACK (1). Individual spectra were averaged, and the background x-ray absorbance was removed by a linear fit through the pre-edge region. The x-ray absorption near-edge structure (XANES) region of the spectrum (11,860-11,890 eV) was obtained by normalizing the fluorescence signal to the edgejump height. The absorption edges (i.e., inflection energies) in the XANES spectra were determined to compare the oxidation state of arsenic between samples and reference compounds. Extended x-ray absorption fine structure (EXAFS) spectra were isolated by fitting a quadratic spline function above the edge. The EXAFS spectra were normalized using a Victoreen polynomial function and transformed from energy to momentum space ( $k$-space) using an $\mathrm{E}_{0}$ of $11,885 \mathrm{eV}$. The resultant EXAFS functions $(\chi(k))$ were weighted by $k^{3}$ to amplify the upper $k$-range, and Fourier-transformed to produce radial structural functions (RSF) in $R$ space over a $k$ range of 3.5-11.5 $\AA^{-1}$. Structural parameters were determined by fitting the weighted EXAFS functions $\left(k^{3} \chi(k)\right)$ using phase and amplitude functions derived from FEFF 8 (2). The amplitude-reduction factor $\left(S_{\mathrm{o}}{ }^{2}=0.92\right)$ was optimized from the fitting of the reference spectra and constrained for all data analysis. Note that the Debye-Waller factors $\left(\sigma^{2}\right)$ were fixed based on either the similarity of the sample spectra to known reference compounds or the optimization among the sample spectra in order to reduce the degree of freedom in the data fitting. Other parameters such as coordination number $(N)$, interatomic distance $(R)$, and energy shift $\left(\Delta \mathrm{E}_{0}\right)$ were allowed to vary. The data fitting was optimized by minimizing the goodness of fit parameter $\left(\mathrm{R}_{\mathrm{f}}\right)$. Errors estimates of the fitted parameters are typically $R \pm 0.02 \AA$ and $N$ $\pm 20 \%$ (3-5).

## XPS analysis.

Raw spectra, after being smoothed, were fitted into a Shirley baseline and a GaussianLorentzian peak shape. Arsenic- $3 d$ spectra were fitted with the doublets of As $3 d_{5 / 2}$ and $3 d_{3 / 2}$ peaks with a spin-orbit splitting of 0.70 eV . The As $3 d_{3 / 2}$ peak was constrained to be $2 / 3$ the area of the As $3 d_{5 / 2}$ peak. The full width at half maximum (FWHM) of all peak components were constrained in the fit. The resultant peak positions (i.e., binding energies) of As $3 d_{5 / 2}$ lines for reference compounds are summarized in Table S2. Using the binding energies observed for five reference compounds, the As speciation of unoxidized samples was further determined. For quantitative analysis, the standard error of each component's contribution to the overall XPS spectrum was determined using Monte-Carlo analysis (CasaXPS, Casa Software Ltd., UK). This program applies artificial noise to a spectrum and calculates an error matrix to give the variance of each fit based on the fitting constraints used.

*The amplitude-reduction factor $\left(S_{0}{ }^{2}\right)$ was set at 0.92 . ${ }^{\dagger}$ The Debye-Waller factors $\left(\sigma^{2}\right)$ were fixed during the numerical fit. $\Delta \mathrm{E}_{0}$ and $\mathrm{R}_{\mathrm{f}}$ indicate energy shift and goodness of the fit, respectively.

Figure S1. X-ray diffraction patterns for reference compounds with $\mathrm{Cu}-\mathrm{K}_{\alpha}$ radiation (40 kV and 100 mV$)$. The diffraction pattern of $\operatorname{As}(0)$ matches that of PDF No. 00-005-0632, which is indicated by red dashed lines.

Figure S2. EXAFS component analysis of unoxidized samples at pH 4.9 (a), 7.1 (b), and 9.1 (c): the original sample spectra (black solid lines), As-S components (blue or pink dashed lines), As-As components at $\sim 2.52 \AA$ (grey dashed lines), and As-As components at $\sim 3.5 \AA$ (yellow dashed lines). The EXAFS spectra of $\operatorname{As}(0)$ (grey solid lines), disordered AsS (blue solid lines), and disordered $\mathrm{As}_{2} \mathrm{~S}_{3}$ (pink solid lines) are included for comparison.

Figure S3. Fourier transform (FT) component analysis of unoxidized samples at pH 4.9 (a), 7.1 (b), and 9.1 (c): the original sample spectra (black solid lines), As-S components (blue or pink dashed lines), As-As components at $\sim 2.52 \AA$ (grey dashed lines), and As-As components at $\sim 3.5 \AA$ (yellow dashed lines). The FT spectra of As $(0)$ (grey solid lines), disordered AsS (blue solid lines), and disordered $\mathrm{As}_{2} \mathrm{~S}_{3}$ (pink solid lines) are included for comparison.

Figure S4. Geometries of thioarsenite surface complexes. Monodentate (single-corner sharing) (a), bidentate-mononuclear (edge sharing) (b), and bidentate-binuclear (doublecorner sharing) (c) complexes with undistorted $\mathrm{FeS}_{4}$ tetrahedra in mackinawite ( FeS ). In this figure, As-S $=2.27 \AA$ (from the EXAFS analysis in this study), $\mathrm{Fe}-\mathrm{S}$ in $\mathrm{FeS}=2.24 \AA$ (16), $\mathrm{Fe}-\mathrm{Fe}$ in $\mathrm{FeS}=2.60 \AA$ (16), and $\mathrm{S}-\mathrm{S}$ in $\mathrm{FeS}=3.66 \AA$ (16) were used to calculate the As-Fe bonding distances. The As-Fe distance observed in our EXAFS study (3.57-3.67 $\AA$ ) is not consistent with the surface complexes of thioarsenites.

Figure S5. Fourier transforms of $k^{3}$-wieghted As-K edge EXAFS spectra for unoxidized samples: sample (a) $\left(\mathrm{As}(\mathrm{III}) /[\mathrm{FeS}]=2.3 \times 10^{-3} \mathrm{~mol} / \mathrm{g}\right.$ at pH 5$)$, sample $(\mathbf{b})(\mathrm{As}(\mathrm{III}) /[\mathrm{FeS}]$ $=2 \times 10^{-4} \mathrm{~mol} / \mathrm{g}$ at pH 9.1 from this study), sample (c) $\left(\mathrm{As}(\mathrm{III}) /[\mathrm{FeS}]=2 \times 10^{-4} \mathrm{~mol} / \mathrm{g}\right.$ at pH 7.1 from this study), and sample (d) $\left(\mathrm{As}(\mathrm{III}) /[\mathrm{FeS}]=2 \times 10^{-4} \mathrm{~mol} / \mathrm{g}\right.$ at pH 4.9 from this study). Unlike samples (b)-(d), no significant right shoulder feature is observed for the first coordination shell of sample (a), whose absorption edge matches closely that of disordered AsS. Since electrons are needed for $\mathrm{As}(\mathrm{III})$ to form $\mathrm{As}(0)$ and AsS , the initially added $\mathrm{As}($ III $)$ acts as an oxidant. Thus, sample (a) due to the higher $\mathrm{As}(\mathrm{III}) /[\mathrm{FeS}]$ ration is at relatively more oxidized redox state, leading to formation of AsS only.
