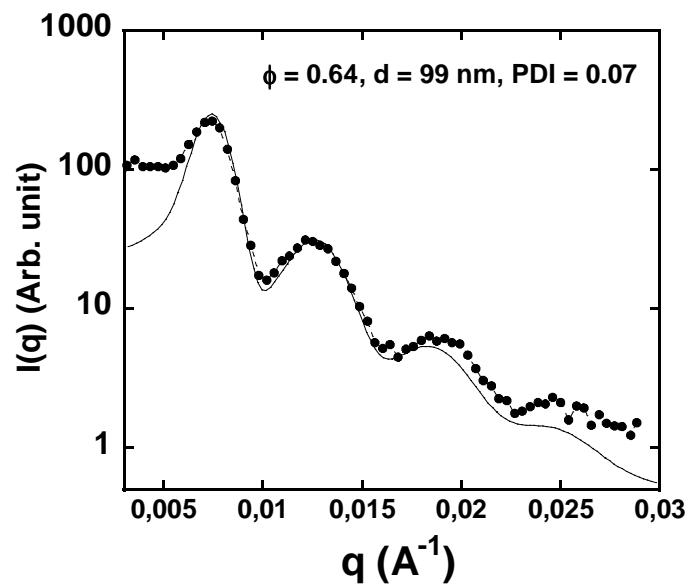

Figure S1. SANS spectra of freshly prepared powder from 93 nm particles (■) plotted in the log ($I(q)$) vs. q form, and compared to Percus-Yevick theory (solid line) using volume fraction $\phi = 0.64$, particle diameter $d = 99 \text{ nm}$ and polydispersity index $\text{PDI} = 0.07$. The data for $q < 3 \cdot 10^{-3} \text{\AA}^{-1}$ correspond to the beam stop.

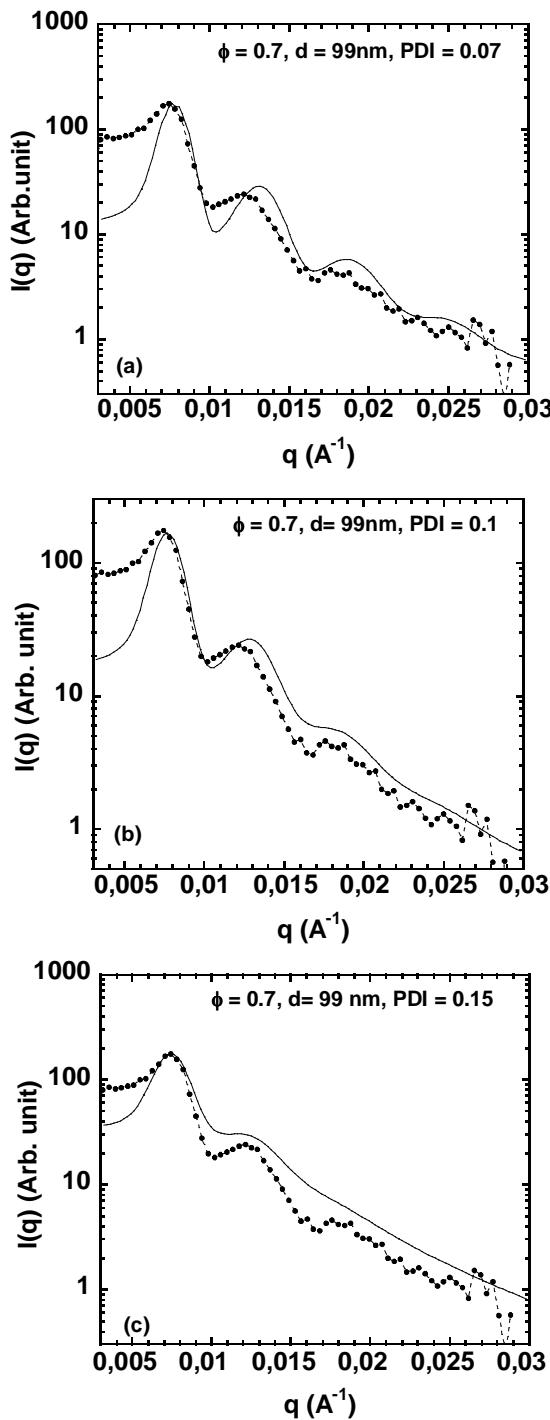

Figure S2. The SANS spectra of the 93 nm powder, annealed a 100 °C for 10 min (■), compared to the Percus-Yevick theory (solid line) using volume fraction $\phi = 0.7$, particle diameter $d = 99$ nm and polydispersity index $\text{PDI} = 0.07$ (a); $\phi = 0.7, d = 99$ nm, $\text{PDI} = 0.1$ (b) and $\phi = 0.7, d = 99$ nm, $\text{PDI} = 0.15$ (c).
