General Considerations. Copper(I) iodide (Strem) was used without further purification. Oxygen (BOC), $\mathrm{CH}_{3} \mathrm{CN}$ (Aldrich), and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (Aldrich) were used without purification. 4-Biphenyl-phenyl ether (Pfaltz and Bauer) was recrystallized prior to use from ethanol (Fisher). When necessary, solvents and reagents were dried prior to use. $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was deoxygenated by purging with $\mathrm{N}_{2}$ and then dried by passing through activated alumina. $\mathrm{CH}_{3} \mathrm{CN}$ was distilled from $\mathrm{CaH}_{2}$. 1,5-Diaza-cis-decalin was prepared as previously described. ${ }^{1}$

Analytical thin layer chromatography (TLC) was performed on EM Reagents 0.25 mm silica-gel 60-F plates. Visualization was accomplished with UV light. Chromatography on silica gel was performed using a forced flow of the indicated solvent system on EM Reagents Silica Gel 60 (230-400 mesh). ${ }^{2}$ GC analysis for reactions was conducted with either a Shimadzu GC-17A gas chromatograph or an Agilent 6850 gas chromatograph with an HP-1 column (Agilent): length $=30 \mathrm{~m}, \mathrm{ID}=0.32 \mathrm{~mm}$, film $=0.25 \mathrm{~mm}$; flow $=2 \mathrm{~mL} / \mathrm{min}, 165^{\circ} \mathrm{C}$ to $290^{\circ} \mathrm{C}$. HPLC analysis of reactions was conducted on an Agilent 1100 liquid chromatograph with a UV detector ( 254 nm ), a Chiralpak AD column (Chiral Technologies Inc., $0.46 \mathrm{~cm}, 25 \mathrm{~cm}$ ), and hexanes (Fisher) and $i$-PrOH (Fisher) as the mobile phase. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker AM-500 ( 500 MHz ) spectrometer. Chemical shifts are reported in ppm from tetramethylsilane ( 0 ppm ) or from the solvent resonance $\left(\mathrm{CDCl}_{3} 7.26 \mathrm{ppm}\right.$, $\mathrm{CD}_{3} \mathrm{CN} 1.94 \mathrm{ppm}$ ). Data are reported as follows: chemical shift, multiplicity ( $\mathrm{s}=\operatorname{singlet}, \mathrm{d}=\operatorname{doublet}, \mathrm{t}$ $=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{br}=$ broad, $\mathrm{m}=$ multiplet), coupling constants, number of protons, and assignment. Proton decoupled ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker AM-500 ( 500 MHz ) spectrometer. Chemical shifts are reported in ppm from the solvent resonance $\left(\mathrm{CDCl}_{3} 77.23 \mathrm{ppm}, \mathrm{CD}_{3} \mathrm{CN} 118.3 \mathrm{ppm}\right)$. Dioxygen uptake kinetics were performed using a computer-interfaced gas-uptake apparatus with a calibrated volume and a pressure transducer designed to measure the gas pressure within a sealed reaction vessel. ${ }^{3}$ Data were acquired using custom software written within LabVIEW (National Instruments).

Calibration Procedure. Calibration curves for each analyte and 4-biphenyl phenyl ether (BPPE) were obtained by subjecting a series of analyte/BPPE mixtures with known molar concentration ratios (determined gravimetrically or by ${ }^{1} \mathrm{H}$ NMR) to GC or HPLC analysis. The area ratios from GC or HPLC were plotted against the molar concentration (see eq S1) ratios and the slope as determined by least squares was taken as the correction factor ( $c f$ ) (see eq S2). For any given sample, then, the analyte concentration could be determined provided that the BPPE concentration was known (eq S3).

$$
\begin{equation*}
\frac{\mathrm{A}_{\text {analyte }}}{\mathrm{A}_{\mathrm{STD}}}=\frac{\varepsilon_{\text {analyte }}}{\varepsilon_{\text {STD }}} \times \frac{[\text { analyte }]}{[\text { STD }]} \tag{S1}
\end{equation*}
$$

$$
\begin{align*}
& \mathrm{A}_{\text {analyte }}=\text { analyte area from HPLC or GC trace, } \mathrm{A}_{\text {STD }}=\text { BPPE area from HPLC or GC trace } \\
& \varepsilon_{\text {analyte }}=\text { analyte molar absorptivity }\left(\mathrm{M}^{-1}\right), \varepsilon_{\text {STD }}=\operatorname{BPPE} \text { molar absorptivity }\left(\mathrm{M}^{-1}\right) \\
& \text { [analyte] = analyte concentration (M), [STD] = BPPE concentration (M) } \\
& \frac{\varepsilon_{\text {analyte }}}{\varepsilon_{\text {STD }}}=\text { slope }=c f  \tag{S2}\\

$$

Single Turnover Experiment with 1. A Schlenk tube charged with 2 ( $85.2 \mathrm{mg}, 0.42 \mathrm{mmol}$ ) and $\mathbf{1}$ ( $29.4 \mathrm{mg}, 0.085 \mathrm{mmol}$ ) was taken into an inert atmosphere glovebox. The tube was then charged with degassed $\mathrm{CH}_{3} \mathrm{CN}(5.2 \mathrm{~mL})$, sealed with a Teflon® screw cap, removed from the glovebox, and sonicated to afford a homogenous solution. The resulting solution was heated at $40{ }^{\circ} \mathrm{C}$ for 43 h . The reaction mixture was then cooled to $0^{\circ} \mathrm{C}$ and the sidearm was charged with $1 \mathrm{~N} \mathrm{HCl}(5 \mathrm{~mL})$. Opening the Teflon® screw cap allowed a rapid quench of the reaction mixture. The resulting solution was
extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $3 \times 20 \mathrm{~mL}$ ). The combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and concentrated. ${ }^{1} \mathrm{H}$ NMR ratios for two trials indicated starting material product ratios of 13:1 and 12:1. Chromatography on $\mathrm{SiO}_{2}$ with $20 \% \mathrm{EtOAc} /$ hexanes allowed isolation of the starting material 2 (68.1 $\mathrm{mg}, 0.34 \mathrm{mmol}, 80 \%$ ) in accord with the ${ }^{1} \mathrm{H}$ NMR measurements and product in $91 \%$ ee. Assay procedure for enantiomeric excess of 3: Chiralpak AD, $1.0 \mathrm{~mL} / \mathrm{min}, 10 \% i-\mathrm{PrOH} /$ hexanes, $\mathrm{t}_{\mathrm{R}}(R)=11.2$ $\min , \mathrm{t}_{\mathrm{R}}(S)=18.2 \mathrm{~min}$.

Preparation of 4. $\mathrm{CH}_{3} \mathrm{CN}$ was degassed in a Schlenk tube by the freeze-pump-thaw method (3 cycles). In the glove box, a 1 mL volumetric flask was charged with 1,5 -diaza-cis-decalin ( 5.7 mg , 0.041 mmol ) and $\mathrm{CuI}(7.7 \mathrm{mg}, 0.041 \mathrm{mmol})$, diluted with $\mathrm{CH}_{3} \mathrm{CN}$, and shaken for 1 h at room temperature to afford a clear-colorless, and homogeneous solution of $4(0.041 \mathrm{M})$. The resulting solution was cooled to $-20^{\circ} \mathrm{C}$ to afford colorless crystals of $\mathbf{4}$ suitable for crystallographic analysis (see end of Supporting Information for structure data tables). Crystalline complex 4 is stable indefinitely at room temperature in an inert atmosphere and undergoes surface oxidation very slowly in the presence of air. Solutions of $\mathbf{4}$ rapidly undergo oxidation when exposed to even trace amounts of atmosphere yielding pink to black solutions. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta 3.17$ (ddd, $J=1.5,2.2,11.7 \mathrm{~Hz}, 2 \mathrm{H}$, $l e), 2.80(\mathrm{~m}, 2 \mathrm{H}, 4), 2.69(\mathrm{ddd}, J=1.5,2.9,12.4 \mathrm{~Hz}, 2 \mathrm{H}, 1 a), 2.22$ (ddddd, $J=4.7,4.7,13.3,13.3,13.3$ $\mathrm{Hz}, 2 \mathrm{H}, 2 a), 2.08(\mathrm{~s}, 2 \mathrm{H}, N-H), 1.70(\mathrm{~m}, 2 \mathrm{H}, 3 a), 1.64(\mathrm{dddd}, J=4.8,4.8,13.5,13.5,2 \mathrm{H}, 3 e), 1.55(\mathrm{~m}$, $2 \mathrm{H}, 2 e) ;{ }^{13} \mathrm{C}$ NMR ( $500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta$ 56.8, 49.7, 29.9, 23.0; IR (KBr pellet) 3458, 3248, 2932, 2833.

Oxidation of 4 in the Presence of Unreactive Phenol 5 (Figure S1). A solution of $\mathbf{5}$ in $\mathrm{CH}_{3} \mathrm{CN}$ ( $5.0 \mathrm{~mL}, 239 \mu \mathrm{~mol}, 47.8 \mathrm{mM}$ ) was added to a reaction tube, attached to the $\mathrm{O}_{2}$-uptake apparatus, evacuated, and backfilled with $\mathrm{O}_{2}$ three times to 888 Torr, and thermally equilibrated at $40{ }^{\circ} \mathrm{C}$. The reaction tube was charged with a solution of $\mathbf{4}$ in $\mathrm{CH}_{3} \mathrm{CN}(3.0 \mathrm{~mL}, 90 \mu \mathrm{~mol}, 12 \mathrm{mM})$. Approximately $22.0 \mu \mathrm{~mol}$ of $\mathrm{O}_{2}$ was absorbed corresponding to a $4: 1\left(4: \mathrm{O}_{2}\right)$ stoichiometry of reaction.

Figure S1. Dioxygen uptake for the oxidation of $\mathbf{4}$ in the presence of phenol 5.

Discovery of the Initial Product Burst with 1 (Figure 1A, main text). A stock solution of 4 (0.01 $\mathrm{M})$ in $\mathrm{CH}_{3} \mathrm{CN}$ was prepared in an inert atmosphere glove box. A stock solution of $2(0.12 \mathrm{M})$ combined with 4-biphenyl phenyl ether $(0.029 \mathrm{M})$ in $\mathrm{CH}_{3} \mathrm{CN}$ was prepared. A test tube was charged with 1.8 mL ( $0.217 \mathrm{mmol} 2,0.053 \mathrm{mmol}$ 4-biphenyl phenyl ether) of this stock solution, purged with dioxygen, and equilibrated to $40^{\circ} \mathrm{C}$. The colorless copper(I) stock solution was removed from the glove box and sparged with dioxygen to afford a black solution of $\mathbf{1}$. An aliquot of the resultant solution of $\mathbf{1}(0.5 \mathrm{~mL}$,
0.005 mmol ) was added and the resulting solution was stirred under atmospheric oxygen. Samples (100 $\mu \mathrm{L})$ were taken over the course of one hour. Each sample was immediately quenched in $1 \mathrm{~N} \mathrm{HCl}(0.5$ mL ), diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, transferred to a vial and the subsequent analysis was performed by GC $($ Agilent 6850$): \mathrm{t}_{\mathrm{R}}(\mathbf{1})=1.14 \mathrm{~min}, \mathrm{t}_{\mathrm{R}}(4$-biphenyl phenyl ether $)=4.8 \mathrm{~min}, \mathrm{t}_{\mathrm{R}}(\mathbf{3})=20.4 \mathrm{~min}, c f=1.18$.

Table S1. Product formation with $\mathrm{Cu}(\mathrm{II})$ catalyst $\mathbf{1}$ (Figure 1A, main text).

Correlation of $\mathbf{O}_{2}$ Uptake to Product Formation and Substrate Consumption (Figure 1B, main text). Five reaction tubes were charged with a stock solution ( 4 mL ) of $2(0.226 \mathrm{M}, 904 \mu \mathrm{~mol})$ combined with 4-biphenyl phenyl ether $(0.063 \mathrm{M}, 252 \mu \mathrm{~mol})$ in MeCN. The tubes were sealed, charged with $\mathrm{O}_{2}$ ( 840 Torr), and thermally equilibrated to $40^{\circ} \mathrm{C}$. Each tube was then charged with 4 ( $2 \mathrm{~mL}, 30$ $\mathrm{mM}, 60 \mu \mathrm{~mol})$ to initiate the reaction. One tube was quenched with $1 \mathrm{~N} \mathrm{HCl}(5 \mathrm{~mL})$ at each of the times indicated in Table S2. The amounts of $\mathbf{2}$ and $\mathbf{3}$ were determined independently by GC (Shimadzu): $\mathrm{t}_{\mathrm{R}}(\mathbf{2})=4.1 \mathrm{~min}(c f=0.586), \mathrm{t}_{\mathrm{R}}(4$-biphenyl phenyl ether $)=12.9 \mathrm{~min}, \mathrm{t}_{\mathrm{R}}(\mathbf{3})=24.5 \mathrm{~min}(c f=0.663)$.

Table S2. Conversion analysis between $\mathrm{O}_{2}, \mathbf{2}$, and $\mathbf{3}$ (Figure 1B, main text).

Stoichiometry of Dioxygen Uptake vs. Consumption of 2 (Figure S2). A stock solution of 4 ( 0.03 M ) in $\mathrm{CH}_{3} \mathrm{CN}$ was prepared in an inert atmosphere glove box. An oxygen uptake reaction tube was charged with stock solution of $2(5 \mathrm{~mL}, 0.28 \mathrm{M}, 1400 \mu \mathrm{~mol})$, purged with dioxygen, and equilibrated to $40^{\circ} \mathrm{C}$. Copper(I) complex 4, was removed from the glove box ( $3 \mathrm{~mL}, 0.032 \mathrm{M}, 96$ $\mu \mathrm{mol}$ ) and added to initiate the reaction. Consumption of $303 \mu \mathrm{~mol}$ of $\mathrm{O}_{2}$ was observed (see Figure S2), after which the reaction was quenched with $1 \mathrm{~N} \mathrm{HCl}(8 \mathrm{~mL})$, extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, washed with brine $(5 \mathrm{~mL})$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and concentrated in vacuo. Chromatography ( $10-20 \% \mathrm{EtOAc} /$ hexanes ) afforded $2(42.9 \mathrm{mg}, 212 \mu \mathrm{~mol}, 15 \%)$ indicating that $1188 \mu \mathrm{~mol}(283.1 \mathrm{mg}, 85 \%)$ of $\mathbf{2}$ were consumed. The ratio of $\mathbf{2}$ consumed to $\mathrm{O}_{2}$ is 3.9 which is consistent with:

1) All four oxidizing equivalents of $\mathrm{O}_{2}$ being used in the OBC.
2) Four equivalents of substrate oxidized per equivalent of $\mathrm{O}_{2}$ consumed.
3) Two equivalents of product formed per equivalent of $\mathrm{O}_{2}$ consumed.

Figure S2. Dioxygen uptake for the oxidative biaryl coupling of 2.

General Procedure for Gas-Uptake Rate Measurements. A typical procedure was conducted as follows for the catalyst dependence studies. A volumetric flask $(10 \mathrm{~mL})$ was taken into the glove box, charged with ( $S, S$ )-diaza-cis-decalin ( $49.3 \mathrm{mg}, 352 \mu \mathrm{~mol}$ ) and $\mathrm{CuI}(72.3 \mathrm{mg}, 380 \mu \mathrm{~mol}$ ), and diluted with degassed $\mathrm{CH}_{3} \mathrm{CN}$. The resulting mixture was shaken $(1 \mathrm{~h})$ to afford a clear, colorless, homogeneous solution of $4(0.035 \mathrm{M})$. A separate volumetric flask $(25 \mathrm{~mL})$ was charged with $2(1.21 \mathrm{~g}$, 5.98 mmol ) and diluted with $\mathrm{CH}_{3} \mathrm{CN}$. Each reaction tube (maximum of 6 total) was charged with a stir bar, the stock solution of $2(3.5 \mathrm{~mL}, 0.24 \mathrm{M})$, and the required make-up volume of $\mathrm{CH}_{3} \mathrm{CN}(0.5-3.2$ mL ). Each tube, with a known calibrated volume (solution plus headspace) was attached to the apparatus. The pressure within the sealed tube was measured with a pressure transducer. The reaction tubes were evacuated to 300 Torr and refilled with oxygen to 900 Torr, and this cycle was repeated 3 times. The pressure for each tube was established at 838 Torr and each flask was heated to $40{ }^{\circ} \mathrm{C}$. Meanwhile the solution of $\mathbf{4}$ was taken up in a syringe $(10 \mathrm{~mL})$, the needle was plugged with a rubber septum, and removed from the glove box. When in the apparatus the pressure stabilized ( 849 Torr), 4 ( $0.3-3 \mathrm{~mL}$ ) was added via syringe through a septum to provide a total reaction volume of 7.0 mL . Dioxygen uptake was monitored and the data was collected using custom software written within LabVIEW (National Instruments).

Steady-State Rate Extrapolation. The OBC reaction time-course reveals an unusual two-phase profile for the amount of $\mathrm{O}_{2}$ consumed. There is an apparent burst in dioxygen uptake followed by a steady state (Figure S3). A plot of $\log \mu$ mols $\mathrm{O}_{2}$ against time exhibits two first-order regimes (Figure S4) with a point of inflection at 2.2 minutes. Extrapolation of the rate from Figure S 3 at the time of the point of inflection in Figure S 4 is used to estimate the initial rate of the steady state.

Figure S3. Kinetic time course for the OBC of $2(0.12 \mathrm{M})$ with $\mathbf{4}(0.013 \mathrm{M})$. Conditions $p \mathrm{O}_{2}=849$ torr, $\mathrm{MeCN}, 40^{\circ} \mathrm{C}$.

Figure S4. $\log \left(\mu \mathrm{mol} \mathrm{O} \mathrm{O}_{2}\right.$ consumed) vs. time. Plot was generated using the primary data from Figure S3.

## Single Turnover under $\mathrm{O}_{2}$ with Low Concentration of 4 - Isolation of ortho-Quinone Species:

With high concentrations of 4 (i.e., stoichiometric) in the presence of $\mathrm{O}_{2}$ and substrate 2, formation of the oxidase steady state catalyst (7) occurs to some extent during the initial burst phase (oxidation of 4 ) giving rise to OBC and formation of product 3. To allow isolation of the putative cofactor $\mathrm{NapH}^{\mathrm{ox}}$, experiments were conducted with low concentrations of $\mathbf{4}$ and an excess of substrate $\mathbf{2}$. These reactions were halted within the approximate window ( 5 min ) of the burst phase (see Figure 1B, main text) to optimized formation of $\mathrm{NapH}^{\mathrm{ox}}$.

10
ortho-Quinone Dimer (10): Oxidation of Substrate 2 with 4. A stock solution of CuI (135.3 $\mathrm{mg}, 0.710 \mathrm{mmol}$ ) and ( $R, R$ )-diaza-cis-decalin ( $99.0 \mathrm{mg}, 0.707 \mathrm{mmol}$ ) in degassed $\mathrm{CH}_{3} \mathrm{CN}(24 \mathrm{~mL})$ was prepared in a three-neck round bottom flask. Substrate $2(5.99 \mathrm{~g}, 29.62 \mathrm{mmol})$ was dissolved in $\mathrm{CH}_{3} \mathrm{CN}(100 \mathrm{~mL})$, sparged with $\mathrm{O}_{2}$ and thermally equilibrated at $40^{\circ} \mathrm{C}$ for 20 min . The solution of 4 was transferred via syringe and added in one portion to the solution of 2. An immediate color change from yellow to dark green was observed. The resulting solution was stirred for 5 min and quenched with $1 \mathrm{~N} \mathrm{HCl}(125 \mathrm{~mL})$. The resulting orange mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \mathrm{x}$ 250 mL ) and washed with brine ( 1 x 200 mL ) and concentrated to give a dark brown solid. The resulting solid was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ however some colored solid material remained. Chromatography ( $10 \% \mathrm{EtOAc} /$ hexanes) afforded $2(5.925 \mathrm{~g}, 29.30 \mathrm{mmol} ; 0.32 \mathrm{mmol} 2$ consumed) and an inseparable mixture of trace $3(<2 \mathrm{mg})$ and oxidized $2(32.3 \mathrm{mg})$. Chromatography ( $20 \%$ $\mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) of the resulting material again gave an inseparable mixture of colored products ( 9 $\mathrm{mg})$. Preparative TLC ( $2.5 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) afforded compound $\mathbf{O Q D}(3 \mathrm{mg}, 7.2 \mu \mathrm{~mol})$ as an orange resin: IR (thin film) 3215, 2957, 2926, 1737, 1675; ${ }^{1} \mathrm{H} \mathrm{NMR} \mathrm{(500} \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 10.80$ (s, $1 \mathrm{H}), 8.67(\mathrm{~s}, 1 \mathrm{H}), 8.25(\mathrm{~m}, 1 \mathrm{H}), 7.90(\mathrm{~m}, 1 \mathrm{H}), 7.57(\mathrm{~m}, 1 \mathrm{H}), 7.54-7.51(\mathrm{~m}, 2 \mathrm{H}), 7.46-7.40(\mathrm{~m}$, $2 \mathrm{H}), 6.85(\mathrm{~m}, 1 \mathrm{H}), 4.06(\mathrm{~s}, 3 \mathrm{H}), 3.37(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 171.0,164.0,153.2$, $150.9,136.1,135.2,134.8,134.6,134.5,131.9,131.1,130.7$ (2C), 130.6, 130.1(2C), 129.9, 129.1,
126.9, 124.9, 124.2, 114.0, 53.2, 52.4; HRMS $\left(\mathrm{ES}^{+}\right)$calcd for $\mathrm{C}_{24} \mathrm{H}_{16} \mathrm{O}_{7} \mathrm{Na}\left(\mathrm{MNa}^{+}\right) 439.0794$, found 439.0777.

9
ortho-Quinone (9): Oxidation of Substrate 2 with 4. Performed analogously to the procedure resulting in 10. Crystals were isolated from a reaction mixture in $20 \% \mathrm{EtOAc} / \mathrm{hexanes}$. IR (thin film) $3255,3130,2926,2856,1602 ;{ }^{1} \mathrm{H}$ NMR ( 500 MHz, DMSO-d $\mathrm{d}_{6}$ ) $\delta 10.03$ (brs, 1H), 9.41 (brs, $1 \mathrm{H}), 8.33-8.31(\mathrm{~m}, 1 \mathrm{H}), 8.01-8.00(\mathrm{~m}, 1 \mathrm{H}), 7.90(\mathrm{t}, 1 \mathrm{H}), 7.78(\mathrm{~m}, 1 \mathrm{H}), 3.74(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( 500 MHz, DMSO-d $\mathrm{d}_{6}$ ) $\delta 180.7$, 169.1, 160.7, 134.8, 132.9, 131.6, 130.0, 127.8, 125.3, 100.1, 51.3. See below from X-ray structural characterization.

X-Ray Structure Determination of 4. Compound $4, \mathrm{C}_{8} \mathrm{H}_{16} \mathrm{~N}_{2} \mathrm{ICu}$, crystallizes in the orthorhombic space group $\mathrm{C} 222_{1}$ (systematic absences $\mathrm{hkl}: \mathrm{h}+\mathrm{k}=$ odd, $001: 1=$ odd) with $\mathrm{a}=8.998(2) \AA, \mathrm{b}=$ $12.980(2) \AA, \mathrm{c}=9.804(2) \AA, \mathrm{V}=1145.0(3) \AA^{3}, \mathrm{Z}=4$ and $\mathrm{d}_{\text {calc }}=1.918 \mathrm{~g} / \mathrm{cm}^{3}$. X-ray intensity data were collected on a Rigaku Mercury CCD area detector employing graphite-monochromated Mo- $\mathrm{K}_{\alpha}$ radiation $(\lambda=0.71073 \AA$ ) at a temperature of 143 K . Preliminary indexing was performed from a series of twelve $0.5^{\circ}$ rotation images with exposures of 30 seconds. A total of 440 rotation images were collected with a crystal to detector distance of 35 mm , a $2 \theta$ swing angle of $-10^{\circ}$, rotation widths of $0.5^{\circ}$ and exposures of 10 seconds: scan no. 1 was a $\phi$-scan from $-90^{\circ}$ to $90^{\circ}$ at $\omega=0^{\circ}$ and $\chi=0^{\circ}$; scan no. 2 was an $\omega$-scan from $-20^{\circ}$ to $20^{\circ}$ at $\chi=-90^{\circ}$ and $\phi=0^{\circ}$. Rotation images were processed using CrystalClear ${ }^{4}$, producing a listing of unaveraged $\mathrm{F}^{2}$ and $\sigma\left(\mathrm{F}^{2}\right)$ values which were then passed to the CrystalStructure ${ }^{5}$ program package for further processing and structure solution on a Dell Pentium III computer. A total of 3284 reflections were measured over the ranges $5.5 \leq 2 \theta \leq 50.0^{\circ},-9 \leq \mathrm{h} \leq 10,-15 \leq \mathrm{k} \leq 12,-11 \leq 1$ $\leq 10$ yielding 995 unique reflections ( $\mathrm{R}_{\mathrm{int}}=0.0270$ ). The intensity data were corrected for Lorentz and polarization effects and for absorption using REQAB $^{6}$ (minimum and maximum transmission 0.701, 1.000).

The structure was solved by direct methods (SIR97 ${ }^{7}$ ). The molecule lies on a crystallographic 2fold axis parallel to $\boldsymbol{a}$ (at $\mathrm{x}, 1 / 2,1 / 2$ ); the Cu -I bond is conincident with the 2 -fold axis. Refinement was by full-matrix least squares based on $\mathrm{F}^{2}$ using SHELXL-97 ${ }^{8}$. All reflections were used during refinement $\left(F^{2}\right.$,s that were experimentally negative were replaced by $\left.F^{2}=0\right)$. The weighting scheme used was $\mathrm{w}=1 /\left[\sigma^{2}\left(\mathrm{~F}_{\mathrm{o}}^{2}\right)+0.0476 \mathrm{P}^{2}+0.2870 \mathrm{P}\right]$ where $\mathrm{P}=\left(\mathrm{F}_{\mathrm{o}}^{2}+2 \mathrm{~F}_{\mathrm{c}}^{2}\right) / 3$. Non-hydrogen atoms were refined anisotropically and hydrogen atoms were refined using a "riding" model. Refinement converged to $R_{1}=0.0296$ and $w R_{2}=0.0765$ for 911 reflections for which $\mathrm{F}>4 \sigma(\mathrm{~F})$ and $\mathrm{R}_{1}=0.0331$, $w \mathrm{R}_{2}=0.0786$ and GOF $=1.098$ for all 995 unique, non-zero reflections and 57 variables ${ }^{9}$. The maximum $\Delta / \sigma$ in the final cycle of least squares was 0.000 and the two most prominent peaks in the final difference Fourier were +1.438 and -0.980 e $/ \AA^{3}$.

Table S6 lists cell information, data collection parameters, and refinement data. Final positional and equivalent isotropic thermal parameters are given in Table S7. Anisotropic thermal parameters are in Table S8. Tables S9 and S10 list bond distances and bond angles. Figure S8 is an ORTEP ${ }^{10}$ representation of the molecule with $30 \%$ probability thermal ellipsoids displayed.

Figure S8. ORTEP drawing of $\mathbf{4}$ with $30 \%$ probability thermal ellipsoids.

X-Ray Structure Determination of 9. Compound $9, \mathrm{C}_{25} \mathrm{H}_{18} \mathrm{O}_{10} \mathrm{Cl}_{2}$, crystallizes in the triclinic space group $P \overline{1}$ with $a=7.1311(4) \AA, \quad b=12.5109(7) \AA, \quad c=13.6583(8) \AA, \quad \alpha=84.172(3)^{\circ}, \quad \beta=83.812(3)^{\circ}$, $\gamma=79.439(3)^{\circ}, \mathrm{V}=1186.75(12) \AA^{3}, \mathrm{Z}=2$ and $\mathrm{d}_{\text {calc }}=1.537 \mathrm{~g} / \mathrm{cm}^{3}$. X-ray intensity data were collected on a Rigaku Mercury CCD area detector employing graphite-monochromated Mo- $\mathrm{K}_{\alpha}$ radiation $(\lambda=0.71069$ $\AA$ ) at a temperature of 143 K . Preliminary indexing was performed from a series of twelve $0.5^{\circ}$ rotation images with exposures of 60 seconds. A total of 708 rotation images were collected with a crystal to detector distance of 36 mm , a $2 \theta$ swing angle of $-10^{\circ}$, rotation widths of $0.5^{\circ}$ and exposures of 30 seconds: scan no. 1 was a $\phi$-scan from $315^{\circ}$ to $525^{\circ}$ at $\omega=10^{\circ}$ and $\chi=20^{\circ}$; scan no. 2 was an $\omega$-scan from $-20^{\circ}$ to $20^{\circ}$ at $\chi=-90^{\circ}$ and $\phi=135^{\circ}$; scan no. 3 was an $\omega$-scan from $-20^{\circ}$ to $4^{\circ}$ at $\chi=-90^{\circ}$ and $\phi=$ $315^{\circ}$; scan no. 4 was an $\omega$-scan from $-20^{\circ}$ to $20^{\circ}$ at $\chi=-90^{\circ}$ and $\phi=0^{\circ}$; scan no. 5 was an $\omega$-scan from $-20^{\circ}$ to $20^{\circ}$ at $\chi=-90^{\circ}$ and $\phi=225^{\circ}$. Rotation images were processed using CrystalClear, ${ }^{4}$ producing a listing of unaveraged $\mathrm{F}^{2}$ and $\sigma\left(\mathrm{F}^{2}\right)$ values which were then passed to the CrystalStructure ${ }^{5}$ program package for further processing and structure solution on a Dell Pentium III computer. A total of 11133 reflections were measured over the ranges $5.84 \leq 2 \theta \leq 50.68^{\circ},-8 \leq h \leq 8,-15 \leq \mathrm{k} \leq 15,-16 \leq 1 \leq 16$ yielding 4310 unique reflections $\left(\mathrm{R}_{\mathrm{int}}=0.0170\right)$. The intensity data were corrected for Lorentz and polarization effects and for absorption. using $\mathrm{REQAB}^{6}$ (minimum and maximum transmission 0.835, 1.000).

The structure was solved by direct methods (SIR977). Refinement was by full-matrix least squares based on $\mathrm{F}^{2}$ using SHELXL-97. ${ }^{8}$ All reflections were used during refinement ( $\mathrm{F}^{2}$,s that were experimentally negative were replaced by $\left.\mathrm{F}^{2}=0\right)$. The weighting scheme used was $\mathrm{w}=1 /\left[\sigma^{2}\left(\mathrm{~F}_{\mathrm{o}}^{2}\right)+\right.$ $\left.0.0922 \mathrm{P}^{2}+1.1736 \mathrm{P}\right]$ where $\mathrm{P}=\left(\mathrm{F}_{\mathrm{o}}^{2}+2 \mathrm{~F}_{\mathrm{c}}^{2}\right) / 3$. Non-hydrogen atoms were refined anisotropically and hydrogen atoms were refined using a "riding" model. Refinement converged to $\mathrm{R}_{1}=0.0564$ and $w_{2}=0.1585$ for 3777 reflections for which $\mathrm{F}>4 \sigma(\mathrm{~F})$ and $\mathrm{R}_{1}=0.0618, \mathrm{wR}_{2}=0.1645$ and $\mathrm{GOF}=1.061$ for all 4310 unique, non-zero reflections and 339 variables. ${ }^{9}$ The maximum $\Delta / \sigma$ in the final cycle of least squares was 0.000 and the two most prominent peaks in the final difference Fourier were +0.782 and $0.625 \mathrm{e} / \AA^{3}$.

Table S11 lists cell information, data collection parameters, and refinement data. Final positional and equivalent isotropic thermal parameters are given in Table S12. Anisotropic thermal parameters are in Table S13. Tables S14 and S15 list bond distances and bond angles. Figures S9 and S10 are ORTEP ${ }^{10}$ representations of the molecule with $30 \%$ probability thermal ellipsoids displayed.
