## Monomer Wave Functions

The molecular orbitals of the a fragment are written as the linear combination of atomic orbitals (LCAO)

$$
\begin{equation*}
\phi_{n}=\sum_{p} c_{n, p} \chi_{p}, \tag{2}
\end{equation*}
$$

where the basis function $\chi_{p}$ is taken to be the $\mathrm{p}_{z}$ atomic orbital on the atom $p$. The LCAO coefficients $c_{n, p}$ are obtained by solving the restricted Hartree-Fock equation, given by

$$
\begin{equation*}
\mathbf{F} c_{n}=E_{n} c_{n}, \tag{3}
\end{equation*}
$$

where $\mathbf{F}$ is the Fock matrix and $E_{n}$ is the energy of the $n$-th molecular orbital. The matrix element of the Fock matrix for the Pariser-Parr-Pople Hamiltonian is given by

$$
\begin{gather*}
\mathbf{F}_{p, p}=\alpha_{p, p}+(1 / 2) \gamma_{p, p} P_{p, p}-\sum_{q \neq p}\left(\gamma_{p, q} q_{q}-P_{q, q} \gamma_{p, q}\right),  \tag{4a}\\
\mathbf{F}_{p, q}=\beta_{p, q}-(1 / 2) \gamma_{p, q} P_{p, q}, \tag{4b}
\end{gather*}
$$

where the core integral $\alpha_{p, p}$ is the negative value of the valence state ionization potential of the atom $p$ and the $\beta_{p, q}$ the resonance integral between the $\mathrm{p}_{\mathrm{z}}$ orbitals on atoms $p$ and $q$. The $P_{p, q}=2 \Sigma_{n} c_{n, p} c_{n, q}$ gives the mobile bond order between atom $p$ and $q$ and $\gamma_{p, q}$ is the electron-electron repulsion integral. The non-nearest-neighbor interactions are taken into account in the PPP model. The $\alpha_{p, p}, \beta_{p, q}$ and $\gamma_{p, q}$ integrals can be estimated by semiempirical parameterization shown below. The core integral $\alpha_{p, p}$ can be evaluated by the Slater nuclear charge $\left(z_{p}\right)$ and core charges $\left(\rho_{p}\right)$ according to the semiempirical expression ${ }^{1}$

$$
\begin{equation*}
\alpha_{p, p}=-\exp \left(0.342 z_{p}+0.555 \rho_{p}+0.758\right) \tag{5}
\end{equation*}
$$

The resonance integral, $\beta_{p, q}$, can be evaluated by dividing it into $\sigma$ and $\pi$ components, defined as:

$$
\begin{equation*}
\beta_{p, q}=\beta_{\sigma} \theta_{z^{\prime}, p} \theta_{z^{\prime}, q}+\beta_{\pi}\left(\theta_{x^{\prime}, p} \theta_{x^{\prime}, q}+\theta_{y^{\prime}, p} \theta_{y^{\prime}, q}\right) \tag{6a}
\end{equation*}
$$

Here $\left(\theta_{x^{\prime} p}, \theta_{y^{\prime} p}, \theta_{z^{\prime} p}\right)$ and ( $\left.\theta_{x^{\prime} q}, \theta_{y^{\prime} q}, \theta_{z^{\prime} q}\right)$ are direction cosine of the $\mathrm{p}_{\mathrm{z}}$ orbitals on atoms $p$ and $q$, with respect to rectangular coordinate system $\left(x^{\prime}, y^{\prime}, z^{\prime}\right)$. The $z^{\prime}$ axis was defined the axis along the line between atoms $p$ and $q$. The semiempirical integrals $\beta_{\pi}$ can be evaluated by the Wolfsberg-Helmholtz equation ${ }^{2}$

$$
\begin{equation*}
\beta_{\pi}=K S_{p, q}\left(\alpha_{p, p}+\alpha_{q, q}\right) \tag{6b}
\end{equation*}
$$

where $K$ is taken to be 0.460 and $S_{p, q}$ denotes the overlap integral between atoms $p$ and $q$, the value of $S_{p, q}$ is expressed by an exponential function of the distance $\left(r_{p, q}\right)$ and the effective nuclear charge $\left(z_{r}\right)^{1}$

$$
\begin{align*}
S_{p, q}= & \exp \left[\left(-0.1112 r_{p, q}+0.1339\right) z_{p} z_{q}+\left(0.0449 r_{p, q}-0.3759\right)\left(z_{p}+z_{q}\right)\right.  \tag{6c}\\
& \left.-0.8627 r_{p, q}+2.0631\right]
\end{align*}
$$

and $\beta_{\sigma}$ is evaluated by semiempirical equation

$$
\begin{align*}
& \beta_{\sigma}=\exp \left(-\varepsilon_{\sigma} / 2\right)\left(-3.546 \times 10^{2} \varepsilon_{\sigma}^{4}-1.418 \times 10^{3} \varepsilon_{\sigma}^{3}+4.255 \times 10^{3} \varepsilon_{\sigma}^{2}+\right. \\
&\left.4.255 \times 10^{4} \varepsilon_{\sigma}+8.512 \times 10^{4}\right) \mathrm{cm}^{-1} \tag{6d}
\end{align*}
$$

with $\varepsilon_{\sigma}=5.385 r_{p, q} / \AA$. The $\beta_{\sigma}$ is the resonance integral for two end-on $\mathrm{p}_{\mathrm{z}}$ orbitals $\left(z=z^{\prime}\right)$ which was obtained by fitting observation properties of excimers. ${ }^{3}$

For the electron-electron repulsion integral, $\gamma_{p, p}$, we used the semiempirical expression ${ }^{1}$ and $\gamma_{p, q}$ can be evaluated by Mataga-Nishimoto equation ${ }^{4}$

$$
\begin{align*}
& \quad \gamma_{p, p}=\exp \left(0.154 z_{p}+0.250 \rho_{p}+1.662\right)  \tag{7a}\\
& \gamma_{p, q}=e^{2} /\left(r_{p, q}+\eta_{p, q}\right) \tag{7b}
\end{align*}
$$

where $r_{p, q}$ is the distance between atom p and q and

$$
\begin{align*}
& \eta_{p, p}=e^{2} / \gamma_{p, p}  \tag{7c}\\
& \eta_{p, q}=2 \eta_{p, p} \eta_{q, q} /\left(\eta_{p, p}+\eta_{q, q}\right) \tag{7d}
\end{align*}
$$

The excited-state wave functions of the fragments are expressed as the linear
combination of the singlet configuration functions corresponding to an excitation from SCF orbital $\mathrm{n}_{1}$ to $\mathrm{n}_{2}\left({ }^{1} \psi_{N}={ }^{1} \psi_{n l-n 2}\right)$,

$$
\begin{equation*}
\Psi_{i}=\sum_{N} \xi_{i, N}{ }^{1} \psi_{N} . \tag{8}
\end{equation*}
$$

The configuration interaction coefficients, $\xi_{i, N}$, and the excitation energy, $\Delta E_{i}$, are obtained by solving the following equation

$$
\begin{equation*}
\mathrm{A} \xi_{i}=\Delta E_{i} \xi_{i}, \tag{9a}
\end{equation*}
$$

where the matrix elements of $\mathbf{A}$ are given by

$$
\begin{align*}
& \mathbf{A}_{N, N}=\left\langle\psi_{N}\right| \mathrm{H}\left|\psi_{N}\right\rangle-\left\langle\psi_{o}\right| \mathrm{H}\left|\psi_{o}\right\rangle=E_{n r}-E_{n a}-\left\langle n_{a} n_{r} \mid n_{a} n_{r}\right\rangle+2\left\langle n_{a} n_{r} \mid n_{r} n_{a}\right\rangle  \tag{9b}\\
& \mathbf{A}_{N, M}=\left\langle\psi_{N}\right| \mathrm{H}\left|\psi_{M}\right\rangle=2\left\langle m_{a} n_{r} \mid m_{r} n_{a}\right\rangle-\left\langle m_{a} n_{r} \mid n_{a} m_{r}\right\rangle  \tag{9c}\\
& \langle\mu v \mid \lambda \sigma\rangle=\iint \phi_{\mu}(1) \phi_{v}(2)\left(1 / r_{12}\right) \phi_{\lambda}(1) \phi_{\sigma}(2) d \tau_{1} d \tau_{2} \approx \sum_{p, q} C_{\mu, q} C_{\nu, p} C_{\lambda, q} C_{\sigma, p} \gamma_{q, p} \tag{9d}
\end{align*}
