## Mn EXAFS Results

Comparison of Mn K-edge EXAFS ( $\mathrm{k}^{3}$-weighted) spectra with those of the WOC in the $\mathrm{S}_{1}$ state is shown in Figure S2 (top), and the Fourier transforms are shown in Figure S2 (bottom). The three main peaks, labeled I - III, have been assigned in the WOC to the Mn-ligand (peak I), di- $\mu$ -oxide-bridged $\mathrm{Mn} \cdots \mathrm{Mn}$ (peak II), and $\mathrm{Mn} \cdots \mathrm{Mn}$ and $\mathrm{Mn} \cdots \mathrm{Ca}$ (peak III) separations. Inspection of the FT spectra in Figure S2 (bottom) indicates significant differences in the peak positions and relative intensities between complex $\mathbf{1}$ and the WOC. Mn-O distances are longer in $\mathbf{1}$ than in the WOC, which is indicated by the shift of peak I to longer distances. This is consistent with the lower average Mn oxidation level in $\mathbf{1}\left(13 \mathrm{Mn}^{\mathrm{III}}, \mathrm{Mn}^{\mathrm{II}}\right)$ compared with the WOC $\mathrm{S}_{1}$ state $\left(2 \mathrm{Mn}^{\mathrm{IV}}\right.$, $2 \mathrm{Mn}^{\text {III }}$ ), Error! Bookmark not defined. which will give longer average Mn-O bonds in the former. In general, $\mathrm{Mn}^{\mathrm{IV}}$ ions (two $\mathrm{Mn}^{\mathrm{IV}}$ in WOC $\mathrm{S}_{1}$ state) are symmetric and isotropic, and have shorter $\mathrm{Mn}-\mathrm{O}$ bond lengths (generally below $2 \AA$ ) when compared to the anisotropic JT distorted $\mathrm{Mn}^{\text {III }}$ ions of complex 1. In the $\mathrm{Mn}_{14} \mathrm{Sr}$ compound, only weak peaks are observed in the region for peaks II and III. This is clearly due to the many different $\mathrm{Mn} \cdots \mathrm{Mn}$ separations in the molecule spanning distances in a wide range of $2.9-4.0 \AA$. In such a case, the contribution of each individual vector is less pronounced in the spectrum normalized to one Mn atom, and the EXAFS oscillations are damped by the high distance distribution

## EXAFS Analysis Details

Data reduction of the EXAFS spectra was performed as described earlier. ${ }^{\text {S1, S2 }}$ Curve fitting was performed using $a b$ initio-calculated phases and amplitudes from the program FEFF $8 .{ }^{\text {S3 }}$ These $a b$ initio phases and amplitudes were used in the EXAFS equation:

$$
\chi(k)=S_{0}^{2} \sum_{j} \frac{N_{j}}{k R_{j}^{2}} f_{e f f_{j}}\left(\pi, k, R_{j}\right) e^{-2 \sigma_{j}^{2} k^{2}} e^{-2 R_{j} / \lambda_{j}(k)} \sin \left(2 k R_{j}+\phi_{i j}(k)\right)
$$

The neighboring atoms to the central atom(s) are divided into $j$ shells, with all atoms with the same atomic number and distance from the central atom grouped into a single shell. Within each shell, the coordination number $N_{j}$ denotes the number of neighboring atoms in shell $j$ at a distance of $R_{j}$ from the central atom. $f_{\text {eff }}\left(\pi, k, R_{j}\right)$ is the ab initio amplitude function for shell $j$, and the Debye-Waller term $e^{-2 \sigma_{j}^{2} k^{2}}$ accounts for damping due to static and thermal disorder in absorber-backscatterer distances. The mean free path term $e^{-2 R_{j} / \lambda_{j}(k)}$ reflects losses due to inelastic scattering, where $\lambda_{j}(k)$ is the electron mean free path. The oscillations in the EXAFS spectrum are reflected in the sinusoidal term $\sin \left(2 k R_{j}+\phi_{i j}(k)\right)$, where $\phi_{i j}(k)$ is the ab initio phase function for shell $j$. This sinusoidal term shows the direct relation between the frequency of the EXAFS oscillations in $k$ space and the absorber-backscatterer distance.

The EXAFS equation was used to fit the experimental data using $N, R$, and $\sigma^{2}$ as variable parameters. The coordination numbers, $N$, are evaluated on a per Sr basis. $N$ values for $\mathrm{Sr}-\mathrm{Mn}$ and Sr -ligand interactions are in multiples of 1 , as there is only one $\mathrm{Sr} / \mathrm{PS}$ II and one Sr in complex 1.

Fit quality was evaluated using two different fit parameters, $\Phi$ and $\varepsilon^{2} . \Phi$ is a normalized sum of residuals between the data and the simulations. The $\varepsilon^{2}$ error takes into account the number of variable parameters. $S_{0}{ }^{2}$ is an amplitude reduction factor due to shake-up/shake-off processes at the central atom(s).

Fit-quality $\Phi$ is:

$$
\Phi=\sum_{1}^{N_{T}}\left(\frac{1}{s_{i}}\right)^{2}\left[\chi^{\text {expt }}\left(k_{i}\right)-\chi^{\text {calc }}\left(k_{i}\right)\right]^{2}
$$

where $N_{T}$ is the total number of data points collected, $\chi^{\text {expt }}\left(k_{i}\right)$ is the experimental EXAFS amplitude at point $i$, and $\chi^{\text {calc }}\left(k_{i}\right)$ is the theoretical EXAFS amplitude at point $i$.

The normalization factor $s_{i}$ is given by:

$$
\frac{1}{s_{i}}=\frac{k_{i}^{3}}{\sum_{j}^{N} k_{j}^{3}\left|\chi^{\text {expt }}\left(k_{j}\right)\right|}
$$

The $\varepsilon^{2}$ error takes into account the number of variable parameters $p$ in the fit and the number of independent data points $N_{\text {ind }}$, as shown in:

$$
\varepsilon^{2}=\left\lceil\frac{N_{\text {ind }}}{N_{\text {ind }}-p}\right\rfloor N^{-1} \Phi
$$

$N$ is the total number of data points collected, and the number of independent data points $N_{\text {ind }}$ is estimated from the Nyquist sampling theorem, as shown in

$$
N_{i n d}=\frac{2 \Delta k \Delta R}{\pi}
$$

$\Delta k$ is the $k$-range of the data and $\Delta R$ is the width of the Fourier-filtered peak in $\AA . \varepsilon^{2}$ provides a gauge of whether the addition of another shell to the fit is justified.
