X-ray diffraction data: Wild-type human DPP-4, was purified and crystallized as previously reported, utilizing TSD's automated Nanovolume Crystallization TM technology. ${ }^{1,2}$ All protein-inhibitor complexes were obtained by soaking preformed DPP-4 crystals in a solution containing compound of interest. Crystals were then cryoprotected with ethylene glycol and flash frozen in liquid nitrogen. X-ray diffraction data were collected at Advanced Light Source (ALS) beam line 5.0.3, and processed using the program HKL2000. ${ }^{3}$ The structures of DPP-4 inhibitor complexes were determined by molecular replacement using MOLREP, utilizing the previously determined coordinates of DPP-4 with accession code 1R9M. ${ }^{1,4}$ Subsequent structure refinement and model building were performed utilizing REFMAC and XtalView. ${ }^{4,5}$ Bound inhibitors were clearly visible in the electron density maps.

$\mathrm{R}_{\text {sym }}=\Sigma|\mathrm{I}-<\mathrm{I}>| / \Sigma \mathrm{I}$, where I is the integrated intensity for a reflection. $\mathrm{R}_{\text {factor }}=\Sigma\left|\mathrm{F}_{\mathrm{p}}-\mathrm{F}_{\mathrm{c}}\right| / \Sigma \mathrm{F}_{\mathrm{P}}$, where $F_{p}$ and $F_{c}$ are the observed and calculated structure factor amplitudes, while $R_{\text {free }}$ is calculated on $5 \%$ of the data excluded from refinement. DPP-4 Assay: Solutions of test compounds in varying concentrations ( $\leq 10 \mathrm{mM}$ final concentration) were prepared in Dimethyl Sulfoxide (DMSO) and then diluted into assay buffer comprising: 20 mM Tris, $\mathrm{pH} 7.4 ; 20 \mathrm{mM} \mathrm{KCl}$; and $0.1 \mathrm{mg} / \mathrm{mL}$ BSA. Human DPP-4 ( 0.1 nM final concentration) was added to the dilutions and pre-incubated for 10 minutes at ambient temperature before the reaction was initiated with A-P-7-amido-4trifluoromethylcoumarin (AP-AFC; $10 \mu \mathrm{M}$ final concentration). The total volume of the reaction mixture was $10-100 \mu \mathrm{~L}$ depending on assay formats used ( 384 or 96 well plates). The reaction was followed kinetically (excitation $\lambda=400 \mathrm{~nm}$; emission $\lambda=505 \mathrm{~nm}$ ) for 510 minutes or an end-point was measured after 10 minutes. Inhibition constants $\left(\mathrm{IC}_{50}\right)$ were calculated from the enzyme progress curves using standard mathematical models.

Microsomal Stability: The test compounds ( $1 \mu \mathrm{M}$ ) were incubated at $37{ }^{\circ} \mathrm{C}$ in phosphate buffer ( $50 \mathrm{mM}, \mathrm{pH} 7.4$ ) containing rat or human liver microsomes $(1 \mathrm{mg} / \mathrm{mL}$ protein) and NADPH (Nicotinamide Adenine Dinucleotide Phosphate, reduced form) (4 $\mathrm{mM})$. The incubation mixtures were quenched with trichloroacetic acid ( 0.3 M ) over 0 , 5, 15, 30 minute time-course. Quenched solutions were centrifuged and supernatants were transferred for LC/MS quantitation. The half-life of test compounds was derived from the compound stability curve over the time course.

General Chemistry Procedures: All references to ether are diethyl ether; brine refers to a saturated aqueous solution of NaCl . Unless otherwise indicated, all temperatures are expressed in ${ }^{\circ} \mathrm{C}$ (degrees Centigrade). All reactions conducted under an inert atmosphere at room temperature unless otherwise noted. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker Avance 400. Chemical shifts are expressed in parts per million (ppm). Coupling constants are in units of Hertz (Hz). Splitting patterns describe apparent multiplicities and are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad). Low-resolution mass spectra (MS) and compound purity data were acquired on a Waters ZQ LC/MS single quadrupole system equipped with electrospray ionization (ESI) source, UV detector ( 220 and 254 nm ), and evaporative light scattering detector (ELSD). Preparative HPLC was conducted on the same system using mixtures of TFA ( $0.05 \%$ ) buffered water and acetonitrile. Thin-layer chromatography was performed on 0.25 mm E. Merck silica gel plates (60F-254), visualized with UV light, $5 \%$ ethanolic phosphomolybdic acid, Ninhydrin or p-anisaldehyde solution. Flash column chromatography was performed on silica gel (230-400 mesh, Merck).
