Text S1. Determination of Rate Law

The rate expression for the reaction of Fe(VI) with sulfonamide can be expressed as

$$-d[Fe(VI)]/dt = k[Fe(VI)]_{tot}{}^m[S]_{tot}{}^n \qquad (1)$$

where [Fe(VI)] and $[S]_t$ are the concentrations of Fe(VI) and sulfonamide, m and n are the orders of the reaction, and k is the overall reaction rate constant. The kinetic studies were carried out under pseudo-order conditions with sulfonamide in excess i.e. $[S]_{ttot} \gg [Fe(VI)]_{tot}$.. The Fe(VI) concentrations were ranged from 0.50 to 0.75 x 10^{-4} M while sulfonamide concentrations were at least ten times of Fe(VI) concentration. Equation (1) can thus be re-written under pseudo-order conditions as:

$$-d[Fe(VI)]/dt = k_1[Fe(VI)]^m \qquad (2)$$

$$\text{where } k_1 = k[S]_{tot}{}^n \qquad (3)$$

The rate law measurements were determined at pH 9.1 and 25 ^{o}C. Reactions were monitored by measuring the absorbance of Fe(VI) at 510 nm wavelength as a function of time. The reactions were followed for at least two half-lives. A successive integration model using the Global kinetic software for the absorbance of Fe(VI) as a function of time gave the best fit for an exponential value of 1, indicating the reaction is first-order with respect to Fe(VI). The k_1 values for the reaction were determined at various concentrations of sulfonamide under same conditions. The k_1 values were corrected for the spontaneous Fe(VI) decay in buffer solutions. The plots of k_1 values versus $[S]_{tot}$ were linear (*24*), which suggests that the rate law for this reaction is first-order with respect to sulfonamide.

Text S2

The observed activation enthalpy, $\Delta H^{\ddagger}_{obs}$, comprises enthalpy of the reaction, $\Delta H^{\ddagger}$, and enthalpies of dissociations of $HFeO_4^-$ and SH, $\Delta H^{\ddagger}_{HFeO4}$ and $\Delta H^{\ddagger}_{SH}$, respectively. The $\Delta H^{\ddagger}_{obs}$ in terms of individual enthalpy can be written as

$$\Delta H^{\ddagger}_{obs} = \Delta H^{\ddagger} - \Delta H^{\ddagger}_{HFeO4} - \Delta H^{\ddagger}_{SH} \quad \text{(pH 7.0)} \tag{4}$$

The values of $pK_{a,SH}$, except sulfamethazine are 3-4 orders of magnitude apart from pH 9.1. It is therefore possible that the contribution of $\Delta H^{\ddagger}_{obs}$ at pH 9.1 would be only from $\Delta H^{\ddagger}$ and $\Delta H^{\ddagger}_{HFeO4}$ (eq 5).

$$\Delta H^{\ddagger}_{obs} = \Delta H^{\ddagger} - \Delta H^{\ddagger}_{HFeO4} \quad \text{(pH 9.1)} \tag{5}$$

Thus, the differences of observed enthalpies at pH 9.1 and 7.0 give values of $\Delta H^{\ddagger}_{SH}$ for sulfonamides except for sulfamethazine. The values of $\Delta H^{\ddagger}_{SH}$ were determined as 21.3 ± 1.1, 39.4 ± 2.4 and 36.9 ± 3.0 kJ mol^{-1} for sulfisoxazole, sulfamethizole, and sulfamethoxazole, respectively. The value of $\Delta H^{\ddagger}_{SH}$ for sulfamethoxazole given in the literature (*34*) using solubility measurement is 33.76 ± 0.25 kJ mol^{-1} and is in reasonable agreement with the value obtained in our study. A similar calculation could not be performed for sulfadimethoxine because it was not possible to perform temperature dependence measurements of its rates with Fe(VI) at pH 7.0. A solution of its powder could not be dissolved at this pH because of its low solubility. The values of pK_{SH} and pK_{HFeO4} for sulfamethazine are similar (Table 1) and the difference in $\Delta H^{\ddagger}_{obs}$ at pH 7.0 and 9.1 is most likely related to the difference in rate constants for the reactions of Fe(VI) species with sulfamethazine species (eqs 2-4 in manuscript). The pH dependence of the rates for the reaction of sulfamethazine with Fe(VI) at different temperature is needed to unravel the difference in $\Delta H^{\ddagger}_{obs}$ at the two pH conditions.

Table S1. **Temperature Dependence of Rate Constants (k, $M^{-1}s^{-1}$) for oxidation of Sulfonamide Antimicrobials by Fe(VI) at pH 7.0 and 9.1.**

| Compound | pH | Temperature | | | |
		15 ^oC	25 ^oC	35 ^oC	45 ^oC
Sulfisoxazole	7.0	1296±31.6	1504±32.0	1763±47.4	1981±37.0
	9.1	22.8±1.10	33.6±5.77	52.0±1.02	81.6±2.21

Figure S6. The three spectra are direct ESI measurements of (a) the SMX in aqueous solution at pH 9 (at 10 µM), (b) the addition of 5 equivalents of Fe(VI) at pH 9 after 7 min, and (c) an injection after 58 min of reaction time. Some minimal decrease in the SMX peak is observed in (b), and a substantial decrease of the SMX peak is observed in (c) with the appearance of a peak at 292.039 depicting product A+Na. Please note that the peaks with non-zero in the first decimal place (e.g. 288.312) do not correspond to SMX or any of its products. The AccuTOF instrument was calibrated for high resolution mass, and therefore 3 in the first decimal place corresponds to other impurities that are present at low concentrations (in the range of our SMX study).
