Definition of Symbols

- R1 ^{15}N longitudinal relaxation rate (s^{-1})
R2 ^{15}N transverse relaxation rate (s^{-1})
NOE NOE
S2 Generalized order parameter
d Prefix indicates uncertainty in the parameter

Summary of Results Obtained by Alternative Data Analysis Methods.

To ensure that the total ΔG_{conf} values were not biased by the choice of data analysis methods, several alternative methods were also investigated (in addition to the method reported in the text of the article). Fixing τ_m to the same value (3.51 ns) for all three mutants increases the magnitudes of $\Delta G_{\text{conf}}(A \rightarrow M)$ and $\Delta G_{\text{conf}}(A \rightarrow T)$ by 67% and 20%, respectively. Using different (independently selected) dynamics models for the same residue in the different mutants does not change the ΔG_{conf} values within error. Finally, limiting all residues to the original Lipari-Szabo model (optimization of only S^2 and the internal correlation time τ_e) increases the magnitudes of $\Delta G_{\text{conf}}(A \rightarrow M)$ and $\Delta G_{\text{conf}}(A \rightarrow T)$ by 63% and 46%, respectively. Irrespective of the analysis method chosen, the $\Delta G_{\text{conf}}(A \rightarrow M)$ and $\Delta G_{\text{conf}}(A \rightarrow T)$ values are always negative and at least as large in magnitude (within error) as the corresponding $\Delta\Delta G_{\text{folding}}$ values. In addition, $\Delta G_{\text{conf}}(A \rightarrow T)$ is always at least twice the magnitude of $\Delta G_{\text{conf}}(A \rightarrow M)$. Thus, the conclusion that backbone conformational entropy makes a significant contribution to the stability differences between these three mutants is supported by the calculated conformational free energies.
