QUANTITATIVE BINDING STUDIES

General: All ¹H NMR studies reported were carried out at 500 MHz on a Varian Inova 500NB spectrometer in the Varian Oxford Instruments Center for Excellence in NMR Spectroscopy (VOICE) laboratory at the University of Illinois. Chloroform-d (CDCl₃) used in studies was passed through a short plug of vacuum dried, activated (Brockmann I), basic alumina prior to use.

Association constants reported for $(2\wedge)_n$ and $3\cdot 3$ are the average of two or more replicate experiments and were obtained by fitting chemical shift data to 1:1 binding isotherms using standard, non-linear curve-fitting procedures (see text for reference). Representative chemical shift plots and curve fits for studies of $(2\wedge)_n$ and $3\cdot 3$ are shown in Figures 1 and 2 (see this and previous page). The association constant for $2\cdot 3$ was estimated by integrating signals for the complexed and uncomplexed components in 1:1 mixtures of **2** and **3** at concentrations at which the self-association of **2** and **3** was negligible. Delay times used in acquiring spectra were at least five times the maximum T_1 relaxation time for the signals of **2**, **3**, and $2\cdot 3$ to insure accurate integration. Representative spectra of 1:1 mixtures of **2** and **3** are shown in the text and in Figure 3.

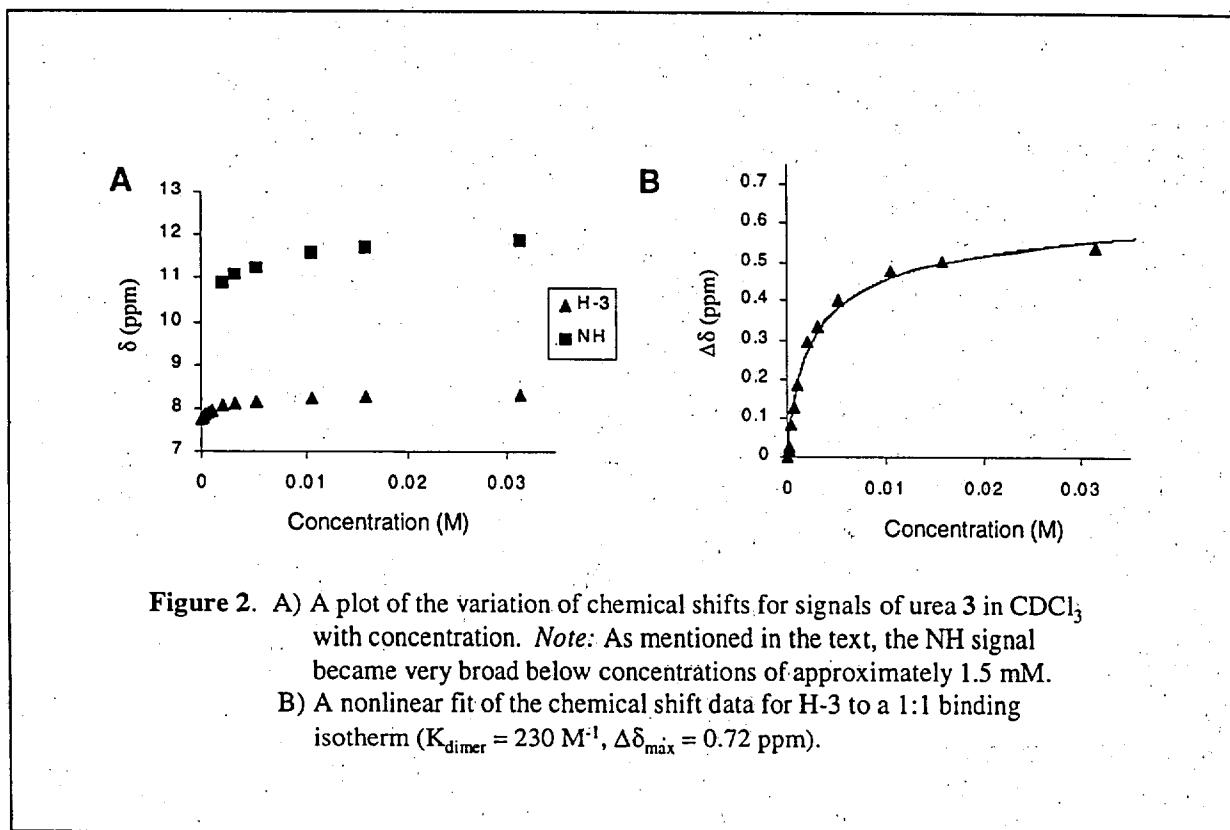

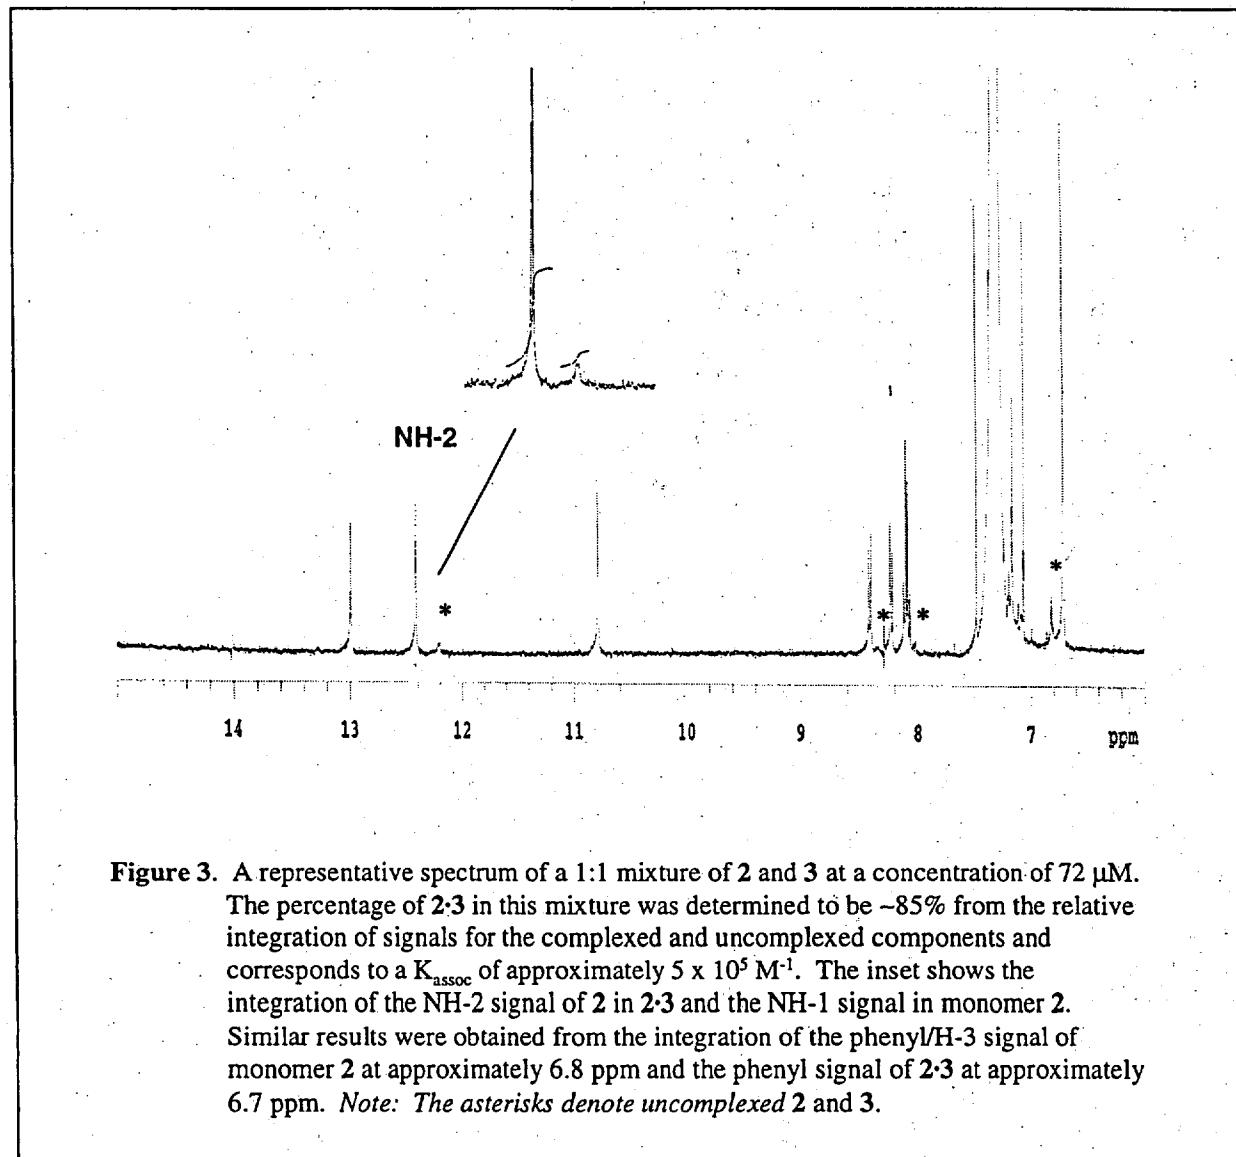

Figure 2. A) A plot of the variation of chemical shifts for signals of urea 3 in CDCl_3 with concentration. Note: As mentioned in the text, the NH signal became very broad below concentrations of approximately 1.5 mM. B) A nonlinear fit of the chemical shift data for H-3 to a 1:1 binding isotherm ($K_{\text{dimer}} = 230 \text{ M}^{-1}$, $\Delta\delta_{\text{max}} = 0.72 \text{ ppm}$).

Crystal preparation and structure refinement summary for 1.

The data crystal was mounted using oil (Paratone-N, Exxon) to a thin glass fiber with the (1 0 -1) scattering planes roughly normal to the spindle axis. Crystals were small and severely twinned. The largest available sample was selected for data collection. Two distinct non-merohedral orientations were identified and integrated. Each integrated set was filtered before the sets were combined to removed statistical outliers and limit resolution to 0.91 \&A;. Reflection with no overlap or complete overlap were combined for refinement.

Systematic conditions suggested the ambiguous space group. Structure was solved by direct methods (Sheldrick, 1998) using non-overlapping data from the primary orientation. H atoms were included as idealized riding contributors. The space group choice was confirmed by successful convergence of the full-matrix least-squares refinement on F^2 (Sheldrick, 1998). The relative volume of the primary component converged at 0.634(2). The highest peak in the final difference Fourier map was in the vicinity of atom C7; the final map had no other significant features. A final analysis of variance between observed and calculated structure factors showed slight dependence on amplitude and resolution.

All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Crystal data and structure refinement summary for 1

The columnar, colorless translucent data crystal was mounted using epoxy to a thin glass fiber with the (6 -1 1) scattering planes roughly normal to the spindle axis. The data crystal was bound by the (1 0 -1), (-1 0 1), (1 0 1), (-1 0 -1), (0 1 0) and (0 -1 0) faces. Distances from the crystal center to these facial boundaries were 0.08, 0.08, 0.15, 0.15, 0.32 and 0.35 mm, respectively. Data were measured at 198 K on an Enraf-Nonius CAD4 diffractometer. Crystal and refinement details are given in Table 1. Systematic conditions suggested the unambiguous space group P 2¹-n. Periodically monitored standard intensities showed no decay. Step-scanned intensity data were reduced by profile analysis (Coppens, 1972) and corrected for Lorentz-polarization effects. Scattering factors and anomalous dispersion terms were taken from standard tables (Wilson, 1992).

The structure was solved by direct methods (Sheldrick, 1990); correct positions for all non-H atoms were deduced from an E-map. One cycle of isotropic least-squares refinement followed by an unweighted difference Fourier synthesis revealed positions for H atoms. All H atoms were refined with isotropic thermal parameters. Non-H atoms were refined with anisotropic thermal coefficients. Successful convergence of the full-matrix least-squares refinement on F² (Sheldrick, 1993) was indicated by the maximum shift/error for the last cycle. The final difference Fourier map had no significant features. A final analysis of variance between observed and calculated structure factors showed no dependence on amplitude or resolution.
