## EXPERIMENTAL

General Considerations. Unless otherwise specified, all reactions and manipulations were performed under purified $\mathrm{N}_{2}$ in a glovebox or using standard Schlenk line techniques. Glassware was oven-dried prior to use. Reaction solvents (diethyl ether, toluene, tetrahydrofuran, dichloromethane, acetonitrile, pentane) were sparged with argon and dried using a Glass Contour Solvent System built by Pure Process Technology, LLC. Deuterated solvents were degassed by repeated freeze-pump-thaw cycles and then stored over $3-\AA$ molecular sieves. Unless otherwise specified, all other chemicals were purchased from commercial sources and used without further purification. 1 L of Nitrous Oxide $\left({ }^{15} \mathrm{~N}_{2}, 98 \%+\right)$ was purchased from Cambridge Isotope Laboratories, Inc. A 460 mL Stainless Steel $1 / 4$ " NPT Stainless Steel Whitey Straight/Male adaptor was also purchased and assembled from Cambridge Isotope Laboratories packaging prior to shipment.

Spectroscopic Measurements. NMR spectra for compound characterization were recorded at ambient temperature using Bruker Avance DPX-400 or Bruker Avance DRX-500 MHz spectrometers. ${ }^{1} \mathrm{H}$ NMR chemical shifts were referenced to residual solvent peaks. FT-IR spectra were recorded on solid samples in a glovebox using a Bruker ALPHA spectrometer fitted with a diamond-ATR detection unit. Elemental analyses were performed by the Midwest Microlab, LLC in Indianapolis, IN. UV-Vis absorbance spectra were taken at room temperature using a JASCO V-660 Spectrophotometer. Absorbance was measured at 0.5 nm intervals and with a continuous scan speed of $1000 \mathrm{~nm} / \mathrm{min}$. X-band spectra were obtained at 10 K with an Elexsys E500 spectrometer, Bruker, Billerica, MA located at the National Biomedical EPR Center at the Medical College of Wisconsin. Q-band spectra were obtained on a Varian E109 spectrometer at $-150^{\circ} \mathrm{C}$ located at the National Biomedical EPR Center at the Medical College of Wisconsin. Spectra were
simulated with EasySpin. ${ }^{1}$ The 1st harmonic spectra were obtained using SumSpec (a program available from the National Biomedical EPR Center) using pseudomodulation with a $1 \%$ or $3 \%$ Bessel function. Samples of $5 \mathrm{mM} \mathbf{1}^{4}$ (not shown), $\mathbf{2}$ and $\mathrm{Cu}(\mathrm{II}) \mathrm{S}_{2} \mathrm{NCN}_{2}$-containing impurity were glassed in 2-methyltetrahydrofuran.

Magnetic Measurements. Magnetic measurements were performed on polycrystalline samples in a sealed polyethylene bag or in a sealed quartz tube restrained with eicosane. All data were collected using a Quantum Design MPMS-XL SQUID magnetometer in a temperature range of 1.8 to 400 K at applied dc fields of 0.1 T and 7 T . A quartz tube was employed for high temperature measurements to avoid melting the polyethylene bag, and a high-field was employed with the quartz-tube sample to ensure sufficient signal-to-noise at high temperatures.

X-ray crystallography. X-ray crystallography data on dark violet tablets of $\mathbf{2}$ was collected at the X-ray Structural Laboratory at Marquette University (Milwaukee, WI). The X-ray singlecrystal diffraction data were collected with an Oxford Diffraction SuperNova diffractometer equipped with dual microfocus $\mathrm{Cu} / \mathrm{Mo}$ X-ray sources, X-ray mirror optics, Atlas CCD detector and low-temperature Cryojet device. Data was collected using $\mathrm{Cu}(\mathrm{K} \alpha)$ radiation at 100 K . The data was processed with CrysAlisPro program package (Oxford Diffraction Ltd., 2010) typically using a numerical Gaussian absorption correction (based on the real shape of the crystal) followed by an empirical multi-scan correction using SCALE3 ABSPACK routine. The structures were solved using SHELXS program and refined with SHELXL program ${ }^{2}$ within Olex2 crystallographic package. ${ }^{3}$ All computations were performed on an Intel PC computer under Windows 7 OS. Hydrogen atoms were localized in difference syntheses of electron density but were refined using appropriate geometric restrictions on the corresponding bond lengths and bond angles within a riding/rotating model (torsion angles of Me hydrogens were optimized to better fit
the residual electron density). The crystal was twinned: regular twins with $180^{\circ}$ rotation around direct -101 vector. Because of quasi-rational cell dimensions, all reflections with $h+\models 2 n$ overlap exactly (but not with identical indexes - HKL transformation matrix -. $50-.50-10-1.50 .5$ ). Reflections with $\mathrm{h}+1=2 \mathrm{n}+1$ are separate. The structure contains two symmetrically independent tetranuclear units having a similar geometry. Two $\mathrm{K}^{+} / 18$-crown -6 counter ions are disordered to a different degree. The disorder affects as the position of K atom (swinging alternatively in axial direction to make $\mathrm{K}^{+}$...Ar contacts with neighboring anions) as well as the crown-ether itself. The structure contains well-ordered 1 eq of solvate DCM solvent. It also contains large areas of highlydisordered solvent only partially localized/identified as diethyl ether. Because of the twinning, an application of a solvent mask procedure was prohibited.

Headspace Analysis by GC-MS. Headspace gas was analyzed by a JEOL GCMate II (JEOL USA, Peabody MA) gas chromatograph/mass spectrometer, the gas chromatograph was an Agile nt 6890Plus (Wilmington DE) equipped with a G1513A autoinjector with 100 vial sample tray connected to a G1512A controller. The gas chromatography column was a J\&W GS-CarbonPLOT (Agilent Tech), 60 m long, 0.320 mm diameter, $1.50 \mu \mathrm{~m}$ film thickness. The carrier gas was helium (99.999\% Ultra High Purity) run through a STG triple filter (Restek Corp.) at a constant flow rate of $2.5 \mathrm{~mL} / \mathrm{min}$. The inlet temperature was $250^{\circ} \mathrm{C}$ and was fitted with an Agilent 4 mm ID single taper split liner containing deactivated glass wool. The static headspace analysis was performed using $5 \mu \mathrm{~L}$ of the experimental gas mixture manually injected via syringe. The GC inlet split ratio was 20:1. The GC oven was run in isothermal mode at a temperature of $30^{\circ} \mathrm{C}$ for 5 minutes then ramped $10^{\circ} \mathrm{C} / \mathrm{min}$ to $80^{\circ} \mathrm{C}$. Total run time was approximately 10 min . The mass spectrometer was a benchtop magnetic sector operating at a nominal resolving power of 500 using an accelerating voltage of 2500 V . The spectrometer was operated in full scan EI mode (+Ve) with
the filament operating at 70 eV scanning from $\mathrm{m} / \mathrm{z} 10$ to $\mathrm{m} / \mathrm{z} 850$ using a linear magnet scan. The scan speed was $0.2 \mathrm{~s} /$ scan. Data analysis was performed using the TSSPro software (Shrader Analytical \& Consulting Laboratories, Inc., Detroit MI) provided with the spectrometer. Mass calibration was performed using perfluorokerosene (PFK).

Preparation of $\left[\mathrm{Cu}_{4}\left(\boldsymbol{\mu}_{\mathbf{4}}-\mathbf{S}\right)\left(\boldsymbol{\mu}_{\mathbf{2}}-\mathrm{NCN}\right)_{\mathbf{4}}\right][\mathrm{K}(\mathbf{1 8}-\mathrm{crown}-\mathbf{6})]$ (2). $\mathbf{1}^{4}(0.10 \mathrm{~g}, 0.079 \mathrm{mmol})$ was dissolved in approximately 60 mL of toluene using a magnetic stir bar. Solid [K(18-crown$\left.6)_{2}\right][\mathrm{Fp}]^{5}(0.057 \mathrm{~g}, 0.076 \mathrm{mmol})$ was added slowly to stirring solution at room temperature. The solution was stirred vigorously overnight. The next day the solution was filtered. The collected dark solid was washed with pentane to remove any $\mathrm{Fp}_{2}$ (cyclopentadienyliron dicarbonyl dimer) until filtrate was clear, and then washed with toluene to remove any unreacted $\mathbf{1}$ until filtrate was clear. The solid was collected and dried under vacuum. Yield of 2: $0.091 \mathrm{~g}, 75 \%$. Compound 2 was stored in a freezer $\left(-36^{\circ} \mathrm{C}\right)$ and is not stable in solution at room temperature for more than an hour. Note: Trace amounts (2-5\%) of $\mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}{ }^{4}$ were often detected by ${ }^{1} \mathrm{H}$ NMR regardless of multiple purification attempts. The best method for removing $\mathrm{Cu}_{2}[(2,4,6-$ $\left.\left.\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}$ is by adding a small amount of tetrahydrofuran ( 2 mL ) to solid $2(0.091 \mathrm{~g})$ so that $\mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}$ dissolves but $\mathbf{2}$ is super-saturated and doesn't dissolve entirely. This solution is filtered, and the resulting purple solid is washed with a small amount of tetrahydrofuran ( 2 mL ) and then pentane ( 2 mL ) to remove any remaining tetrahydrofuran solvent. The purple solid can then be collected and dried under vacuum. Usually this purification method is done once to achieve experimental purity. Dark black crystals may be obtained by dissolving 2 in a minimum amount of dimethoxyethane, pipette-filtering through Celite, and leaving solution at $-36^{\circ} \mathrm{C}$ for four days. NMR samples were dissolved in acetone- $d_{6}$ and pipette-filtered through Celite into NMR tube. ${ }^{1} \mathrm{H}$ NMR ( 500 MHz , acetone- $d_{6}$ ): $\delta 3.66$ (s, $24 \mathrm{H}, 18$-crown-6). FT-IR ( $\mathrm{cm}^{-}$
${ }^{1}$ ): 2992, 2903, 2854, 2724, 1717, 1652, 1609, 1556, 1538, 1469, 1330, 1209, 1104, 959, 847, 738, 586, 504, 422. Anal. calcd. for $\mathrm{C}_{88} \mathrm{H}_{116} \mathrm{Cu}_{4} \mathrm{~N}_{8} \mathrm{O}_{6} \mathrm{SK}: \mathrm{C}, 61.90 ; \mathrm{H}, 6.85$; N, 6.56. Found: C, 60.37; $\mathrm{H}, 6.50 ; \mathrm{N}, 6.57$. Repeated attempts at obtaining satisfactory combustion analysis results (with \%C within $\pm 0.4 \%$ of the calculated value) gave results with a large degree of variance, indicating either that the spectroscopically pure samples were compromised during shipping/handling or that the compound does not combust cleanly.

Detection of 1 after reaction between $\mathrm{N}_{2} \mathrm{O}$ and 2. Inside a $\mathrm{N}_{2}$ filled glovebox, to a Schlenk tube equipped with a Telfon screw cap and magnetic stir bar, $2(0.006 \mathrm{~g}, 0.0035 \mathrm{mmol})$ was added and dissolved in approximately 2.5 mL dichloromethane. The tube was sealed with the Teflon screw cap and taken out of the glovebox and connected to a Schlenk line streaming $\mathrm{N}_{2} \mathrm{O}$. The solution was cooled to $-78^{\circ} \mathrm{C}$ (dry ice and acetone bath) with stirring. The solution was then exposed to $\mathrm{N}_{2} \mathrm{O}$ for 6.5 hours while maintaining the cooling bath at $-78^{\circ} \mathrm{C}$. Once cooling bath was removed, solvent was removed by vacuum evaporation and Schlenk tube was closed and pumped back into the glovebox. Evaporated residue was dissolved in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ and pipette-filtered through Celite into an NMR tube for analysis. A control experiment was conducted by same procedure using $0.005 \mathrm{~g}(0.0029 \mathrm{mmol})$ of $\mathbf{2}$ in approximately 2 mL of dichloromethane while under $\mathrm{N}_{2}$. Using integration of 18 -crown- 6 as an internal standard ( 24 H ) in ${ }^{1} \mathrm{H}$ NMR reveals $45 \%$ NMR yield of $\mathbf{1}^{4}$ in the reaction with $\mathrm{N}_{2} \mathrm{O}$ (Figure S 9 ) with respect to any $\mathrm{Ar}-\mathrm{CH}_{3}$ peak of $\mathbf{1}(12 \mathrm{H})$ and $0 \%$ yield in $\mathrm{N}_{2}$ control experiment (Figure S10).

Recovery of 1 after reaction between $\mathrm{N}_{2} \mathrm{O}$ and 2. Inside a $\mathrm{N}_{2}$ filled glovebox, to a Schlenk tube equipped with a Teflon screw cap and magnet stir bar, $2(0.021 \mathrm{~g}, 0.012 \mathrm{mmol})$ was added and dissolved in dichloromethane $(10 \mathrm{~mL})$. The tube was sealed with the Teflon cap and taken out of the glovebox and connected to Schlenk line streaming with $\mathrm{N}_{2} \mathrm{O}$. The solution in the
flask was cooled to $-78^{\circ} \mathrm{C}$ (dry ice and acetone bath) with stirring, and then opened to $\mathrm{N}_{2} \mathrm{O}$ for 6 hours while maintaining the cooling bath at $-78^{\circ} \mathrm{C}$. Solvent was removed by vacuum evaporation and Schlenk tube was closed and pumped back into the glovebox. Purple evaporated residue inside Schlenk tube was washed with acetonitrile (approximately 20 mL ), in which $\mathbf{1}$ is insoluble, and then pipette-filtering through Celite until filtrate became clear. Dark purple solid remaining was collected using dichloromethane and the solution was completely evaporated by vacuum. The same procedure was followed in a control experiment using $0.021 \mathrm{~g}(0.012 \mathrm{mmol})$ of $\mathbf{2}$ in 10 mL of dichloromethane under $\mathrm{N}_{2}$. Amount of $\mathbf{1}$ isolated from $\mathrm{N}_{2} \mathrm{O}$ reaction residue: $0.015 \mathrm{~g}(0.010$ mmol, $88 \%$ yield, Figure S 11 ); amount of $\mathbf{1}$ isolated from $\mathrm{N}_{2}$ control reaction residue: 0.0052 g ( $0.0035 \mathrm{mmol}, 30 \%$ decomposition, Figure S12).

Oxygen Trapping Experiment with $\mathbf{M e}_{3} \mathbf{S i C l}$. Inside a $\mathrm{N}_{2}$ filled glovebox, to a Schlenk tube equipped with a Teflon screw cap and magnet stir bar, $2(0.003 \mathrm{~g}, 0.0017 \mathrm{mmol})$ was added and dissolved in dichloromethane ( 3 mL ). The tube was sealed with the Teflon cap and taken out of the glovebox and connected to Schlenk line streaming with $\mathrm{N}_{2} \mathrm{O}$. The solution in the flask was cooled to $-78^{\circ} \mathrm{C}$ (dry ice and acetone bath) with stirring, and then opened to $\mathrm{N}_{2} \mathrm{O}$ for 3.5 hours while maintaining the temperature at $-78^{\circ} \mathrm{C}$. Solvent was removed by vacuum evaporation and Schlenk tube was closed and pumped back into the glovebox. Purple evaporated residue inside Schlenk tube was dissolved in approximately 1 mL of $\mathrm{CD}_{2} \mathrm{Cl}_{2}$, and $95 \mu \mathrm{~L}$ of a 0.092 M solution of TMS-Cl $(0.0087 \mathrm{mmol})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ was added. Contents were stirred for 1 hour at room temperature and were then pipette-filtered through Celite into an NMR tube for analysis (Figure S13). The same procedure was followed in a control experiment using $0.006 \mathrm{~g}(0.0035 \mathrm{mmol})$ of $\mathbf{2}$ in 3 mL of dichloromethane, under $\mathrm{N}_{2}$, followed by addition of $190 \mu \mathrm{~L}$ of $0.092 \mathrm{M} \mathrm{TMS}-\mathrm{Cl}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution ( 0.017 mmol ) in the same manner as described in the $\mathrm{N}_{2} \mathrm{O}$ experiment (Figure

S14). ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ): $\delta 0.07\left(\mathrm{~s},\left(\mathrm{Me}_{3} \mathrm{Si}\right)_{2} \mathrm{O}\right), 0.43$ (s, unreacted TMS-Cl), $1.31(\mathrm{~s}, \mathbf{1}$ $\left.\mathrm{Ar}-\mathrm{CH}_{3}\right), 1.39\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.15\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.17\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.69\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.77(\mathrm{~s}$, $\mathbf{1}$ Ar- $\mathrm{CH}_{3}$ ), 3.63 (s, 18-crown-6), 6.10 (s, $\left.\mathbf{1} \mathrm{NC}(\mathrm{H}) \mathrm{N}\right), 6.25$ (s, $\left.\mathbf{1} \mathrm{Ar}-\mathrm{CH}\right), 6.31$ ( $\mathrm{s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}$ ), 6.61 (s, $1 \mathrm{NC}(\mathrm{H}) \mathrm{N}), 6.71$ (s, $\mathbf{1}$ Ar-CH).

Oxygen Trapping Experiment with Benzoyl Chloride. Inside a $\mathrm{N}_{2}$ filled glovebox, to a Schlenk tube equipped with a Teflon screw cap and magnet stir bar, $2(0.010 \mathrm{~g}, 0.0058 \mathrm{mmol})$ was added and dissolved in dichloromethane ( 5 mL ). The tube was sealed with the Teflon cap and taken out of the glovebox and connected to Schlenk line streaming with $\mathrm{N}_{2} \mathrm{O}$. The solution in the flask was cooled to $-78^{\circ} \mathrm{C}$ (dry ice and acetone bath) with stirring, and then opened to $\mathrm{N}_{2} \mathrm{O}$ for 3 hours while maintaining the temperature at $-78^{\circ} \mathrm{C}$. Solvent was removed by vacuum evaporation and Schlenk tube was closed and pumped back into the glovebox. Purple evaporated residue inside Schlenk tube was mixed with approximately 8 mL of diethyl ether and $20 \mu \mathrm{~L}$ of a 0.287 M solution of cold $\left(-32^{\circ} \mathrm{C}\right)$ benzoyl chloride ( 0.0057 mmol ) in diethyl ether was added. Contents stirred for 1 hour at room temperature, pipette-filtered through Celite and solvent was removed by vacuum evaporation. Resulting residue was dissolved in $\mathrm{C}_{6} \mathrm{D}_{6}$ and pipette-filtered through Celite into an NMR tube for analysis (Figure S15-S16). ${ }^{1} \mathrm{H}$ NMR (400 MHz, $\mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 1.46\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}^{\mathrm{Ar}} \mathrm{CH}_{3}\right), 1.57$ (s, $\left.\mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.18\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.20\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.83\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.97\left(\mathrm{~s}, \mathbf{1} \mathrm{Ar}-\mathrm{CH}_{3}\right), 3.52$ (s, 18-crown-6), 6.37 (s, $\mathbf{1}$ Ar-CH), 6.44 (s, $\mathbf{1}$ Ar-CH), 6.94 (m, benzoic anhydride Ar-CH), 7.07 ( m , benzoic anhydride $\mathrm{Ar}-\mathrm{CH}$ ), 7.96 (m, benzoic anhydride Ar-CH).

## Reaction Headspace Analysis of ${ }^{15} \mathbf{N}_{2}$ Produced from the Reaction between ${ }^{15} \mathbf{N}_{2} \mathrm{O}$ and

2. Inside a $\mathrm{N}_{2}$ filled glovebox, to a 100 mL round bottom Schlenk flask with a magnetic stir bar, $\mathbf{2}$ $(0.125 \mathrm{~g}, 0.0732 \mathrm{mmol})$ was added and dissolved in THF ( 60 mL ). The flask was sealed with a fresh septum secured with copper wire and a Keck clip. The flask was taken out of the glovebox
and connected to a T-shaped stopcock connected to a Schlenk line streaming both $\mathrm{N}_{2}$ and ${ }^{15} \mathrm{~N}_{2} \mathrm{O}$ gases. After five freeze-pump-thaw cycles, the flask was cooled to $-78^{\circ} \mathrm{C}$ (dry ice and acetone bath) and headspace was backfilled quickly with ${ }^{15} \mathrm{~N}_{2} \mathrm{O}(\sim 3$ seconds) and then the flask was closed. The reaction was stirred at $-78^{\circ} \mathrm{C}$ for three hours, and then the cooling bath was removed. The reaction was then stirred for 3 hours at room temperature to equilibrate the gases in the reaction headspace and dissolved in the solution. The gases in the reaction headspace were then analyzed by $5 \mu \mathrm{~L}$ injections into GC-MS (Figure S21). After the 6 hour GC-MS headspace measurement, the reaction flask sat for 48 hours at room temperature, without stirring to prevent high pressure build-up within the flask. After 48 hours, the gases in the headspace were again analyzed by $5 \mu \mathrm{~L}$ injections into the GC-MS (Figures S17 and S19). To serve as a blank, a 50 mL round bottom Schlenk flask was sealed using a fresh septum secured with copper wire and a Keck clip. The blank flask was evacuated by vacuum and refilled with ${ }^{15} \mathrm{~N}_{2} \mathrm{O}$ and then closed. Gases in blank flask were analyzed by a $5 \mu \mathrm{~L}$ injection (Figure S22). Blank flask then sat alongside the reaction flask for 48 hours at room temperature and was re-analyzed by GC-MS (Figure S18 and S20).

Computational Methods. All calculations were performed using Gaussian09, Revision B.01. ${ }^{6}$ Density functional theory (DFT) calculations were carried out using the B3LYP functional. ${ }^{7}$ Mixed basis sets were employed: the LANL2TZ(f) triple- $\zeta$ basis set ${ }^{8}$ with effective core potential ${ }^{9}$ was used for Cu , the Gaussian09 internal $6-311+\mathrm{G}(\mathrm{d})$ basis set was used for S , and the Gaussian09 internal $6-31+\mathrm{G}(\mathrm{d})$ basis set was used for $\mathrm{C}, \mathrm{H}$, and N . All calculations included a polarizable continuum model for dichloromethane solvation. ${ }^{10}$ The optimized coordinates for model 1' (where the mesityl groups of $\mathbf{1}$ were replaced with methyls) at a slightly different level of theory were reported previously ${ }^{4}$ and were used as the starting point for obtaining optimized coordinates for neutral 1' and anion 2' (where the mesityl groups of $\mathbf{2}$ were replaced with methyls). Optimized
coordinates for both structures are enclosed below (Tables S2 and S3), along with comparisons of $\mathbf{1}^{\prime}$ and $\mathbf{2}^{\prime}$ to the experimental structures of $\mathbf{1}$ and $\mathbf{2}$ (Table S1). These optimized coordinates were used for single-point TD-DFT calculations (35 states for $\mathbf{1}^{\prime}, 25$ states for $\mathbf{2}^{\prime}$ ) at the same level of theory (see Figures S18-19). Lists of these transitions are included as Tables S4 and S5 below. Natural transition orbital analysis ${ }^{11}$ was used to examine the nature of the dominant transition (State $9,578 \mathrm{~nm}, 6000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ) in the predicted electronic spectrum of 2 . The broken-symmetry $S=0$ and $S=1$ states of $\mathbf{1}^{\prime}$ were found to be higher energy than the closed-shell $S=0$ state presented here, although all three states were within $\pm 2 \mathrm{kcal} / \mathrm{mol}$ of each other, indicating that high-le vel calculations are in order to accurately model $\mathbf{1}$. Orbital surfaces and Mulliken spin density were plotted using Gaussview $4.1^{12}$ and are presented with isovalues indicated in figure captions.

Figure S1. $\chi T$ vs. temperature plots of $\mathbf{1}^{4}$ in a polyethylene bag at a field of 0.1 T (left) and a separate sample of $\mathbf{1}$ in a sealed quartz tube at a field of 7 T (right). Both depict a downward sloping, linear curve, indicative of a diamagnetic sample. The significantly larger diamagne tic moment exhibited by the quartz-tube sample (right) is attributable to the additional mass of the quartz and eicosane.

Figure S2. Solid state structure of $\mathrm{Cu}(\mathrm{II}) \mathrm{S}_{2} \mathrm{NCN}_{2}$ paramagnetic impurity determined by singlecrystal X-ray diffraction. Mesityl groups are shown as wireframes and other atoms are displayed as $50 \%$ probability thermal ellipsoids. Hydrogen atoms have been omitted. $\mathrm{Cu}(\mathrm{II}) \mathrm{S}_{2} \mathrm{NCN}_{2}$ was isolated following the procedure published for $\mathbf{1}^{4}$ by $S_{8}$ with the following modifications: the reaction mixture was stirred for two days at r.t. The crude reaction solution was filtered through Celite and the filtrate was completely evaporated by vacuum. Recrystallization by vapor diffusion of the filtrate residue in $\mathrm{CHCl}_{3}$ and pentane vapors leads to formation of maroon crystals.

Figure S3. X-band EPR spectrum of the $\mathrm{Cu}(\mathrm{II}) \mathrm{S}_{2} \mathrm{NCN}_{2}$ species from Figure S 2 at 34 K (black trace) and 24 K (red trace), power 46 dB .

Figure S4. Q-band EPR spectrum for 2 (black scan): $34.99 \mathrm{GHz},-150{ }^{\circ} \mathrm{C}, 9$ scans, power $22 \mathrm{~dB}, 10 \mathrm{G}$, mod.; time constant $0.1 \mathrm{sec} ; 2 \mathrm{~min}$ scans; Simulation (EasySpin, red scan): $\mathrm{g}=2.09,2.043$; four Cu's (both isotopes), $\mathrm{A}=100,15$ MHz ; lwpp=0.5; HStrain=100 90. $\mathrm{P}_{1 / 2}$, the power for which the X-band EPR signal is one-half of the expected signal if unsaturated, is 22.5 dB at 10 K and 26.5 dB at 5 K . The spin-lattice relaxation time is faster for mixed valence complexes in both $\mathbf{2}$ and $\mathrm{Cu}_{\mathrm{z}}$ than for monomeric cupric complexes. The difference in the EPR spectra between $\mathbf{2}$ and $\mathrm{Cu}_{\mathrm{Z}}$ is most easily seen in the Q-band spectrum, where $\mathrm{gl}>\mathrm{gll}$ for $\mathbf{2}$, but $\mathrm{gl}<\mathrm{gll}$ for $\mathrm{Cu}_{\mathrm{Z}}$ (P. Cheng...E.J. Solomon, J. Am. Chem. Soc., $124(5), 744,2002$ ) suggesting that the unpaired electron in $\mathbf{2}$ is not a pure $\mathrm{dx} 2-\mathrm{y} 2$ orbital. The line width for gll in the Q -band spectrum and simulations are used to approximate All . Al is obtained from resolved lines in the X -band spectrum and from simulations. Another difference between $\mathbf{2}$ and $\mathrm{Cuz}_{\mathrm{z}}$ is that the spectra for $\mathbf{2}$ are simulated with four equivalent coppers and the spectra for $\mathrm{Cu}_{\mathrm{Z}}$ are simulated with two sets of inequivalent coppers.

Figure S5. X-band EPR spectrum of 2 (black scan): $9.632 \mathrm{GHz}, 9.9 \mathrm{~K}, 9$ scans, power 46 dB ; Simulation (red scan, EasySpin): $g=2.09,2.043$; both 63 and 65 isotopes, $A=100,15 \mathrm{MHz}$, lwpp=0.5; Hstrain:100 20.

Figure S6. ${ }^{1} \mathrm{H}$ NMR ( 500 MHz ) of $\mathbf{2}$ in Acetone-d 6 .

Figure S7. Absorption Spectra for 0.082 mM 2 (blue trace; absorption maxima at $565.5 \mathrm{~nm} ; \varepsilon=$ $8601 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ ) and $0.085 \mathrm{mM} \mathbf{1}^{4}$ (orange trace; absorption maxima at $561 \mathrm{~nm} ; \varepsilon=18132 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-}$ ${ }^{1}$ ) in THF at room temperature.

Figure S8. Infrared Spectrum of 2.

Figure S9. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) of reaction products from $\mathbf{2}+\mathrm{N}_{2} \mathrm{O}$ with appearance of $\mathbf{1}$ in $45 \%$ yield compared to integration of 18 -crown- 6 as the internal standard. Residual solvents in spectra are not peak picked. Peak appearing at 2.29 ppm is a decomposition product of 2, $\mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}{ }^{4}$.

Figure S10. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) of control experiment between 2 and $\mathrm{N}_{2}$. Residual solvents in spectra are not peak picked. Peaks appearing at 2.17-2.29 ppm and 6.78-6.96 ppm are decomposition products of $\mathbf{2}$; $\mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}{ }^{4}$ and free ligand (bis(2,4,6trimethylphenyl)formamidine) $)^{4}$. No presence of $\mathbf{1}$ is evident.

Figure S11. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$ of $\mathbf{1}$ isolated after reaction between $\mathbf{2}$ and $\mathrm{N}_{2} \mathrm{O}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ ( $88 \%$ yield). Residual solvents in spectra are not peak picked. Peaks observed at 2.29, 6.78 and 6.95 ppm are the decomposition product of $\mathbf{2}, \mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}{ }^{4}$.

Figure S12. ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) of $\mathbf{1}$ recovered after control experiment between $\mathbf{2}$ and $\mathrm{N}_{2}$ (30\% decomposition). Residual solvents in spectra are not peak picked. Peak observed at 2.29 ppm is the decomposition product of $\mathbf{2}, \mathrm{Cu}_{2}\left[\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}(\mathrm{H})\right]_{2}{ }^{4}$.

Figure S13. ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$ of reaction products from $2+\mathrm{N}_{2} \mathrm{O}$, using 5 equivalents of TMS-Cl as an oxygen trap. Hexamethyldisiloxane appearing at 0.07 ppm is the major product and some unreacted TMS-Cl appears at 0.43 ppm . Residual solvents in spectra are not peak picked.

Figure S14. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) of resulting control experiment between 2 and $\mathrm{N}_{2}$ and 5 equivalents of TMS-Cl. Residual solvents in spectra are not peak picked.

Figure S15. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) of reaction products from $2+\mathrm{N}_{2} \mathrm{O}$ using benzoyl chloride as an oxygen trap to form benzoic anhydride. Residual solvents in spectra are not peak picked.

Figure S16. Comparison of ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) of reaction products from $\mathbf{2}+\mathrm{N}_{2} \mathrm{O}$ using benzoyl chloride as an oxygen trap to form benzoic anhydride (A); authentic sample of benzoic anhydride (B); authentic sample of benzoyl chloride (C).

Figure S17. Total chromatogram (top) and extracted ion chromatogram for $\mathrm{m} / \mathrm{z} 30$ (bottom) from the reaction headspace after 48 hours of ${ }^{15} \mathrm{~N}_{2} \mathrm{O}$ and $\mathbf{2}$.

Figure S18. Total chromatogram (top) and extracted ion chromatogram for $\mathrm{m} / \mathrm{z} 30$ (bottom) from flask containing ${ }^{15} \mathrm{~N}_{2} \mathrm{O}$ for 48 hours.
