NiP nanospheres	434-50	122	11.1 h	1 M NaOH	*Int. J. Hydrogen Energy*, **2016**, *41*, 20515
Ni-S/CeO$_2$	170-30	165.6	--	1 M NaOH	*Int. J. Hydrogen Energy*, **2016**, *41*, 20485

[a] The loading mass was based on the mass of nickel.

[b] η (mV) stands for the overpotential at current density of j (mA cm^{-2}).

[c] TS represents Tafel slope (mV dec^{-1}).

**Table S5.** Exchange current density of the catalysts.

| entry	catalyst	Exchange current density / mA cm^{-2}
1	NiO$_x$@BCNTs	0.308
2	NiO$_x$@NC-800	0.214
3	NiO$_x$@NC-900	0.212
4	NiO$_x$@NC-1000	0.171
Scheme S1. Scheme for the fabrication of NiO$_x$@BCNTs.

In our case, thermal condenstion of melamine formed layered graphic carbon nitride (g-C$_3$N$_4$) at low-temperature zone (<600 ^{o}C).[1] The Ni species were partially reduced to metallic Ni NPs by reductive groups decomposed from g-C$_3$N$_4$ as the the temperature rises. On the other hand, the g-C$_3$N$_4$ also acted as precursor to deposit nitrogen-doped carbon around the Ni NPs.[2] A high pyrolysis temperature or long holding period probably resulted in a sufficient decomposition of g-C$_3$N$_4$, and thus high concentrations of nitrogen and carbon fragments around the Ni NPs, which promoted the growth of nitrogen-doped carbon nanotubes. As a consequence, the Ni NPs were encapsulated in nitrogen-doped carbon shells. The experiment results show that controlled parameter in the experiment can lead to the production of BCNTs.

$$H_2O + e^- \longrightarrow H_{ads} + OH^- \qquad \text{(Volmer)} \qquad (1)$$

$$H_{ads} + H_{ads} \longrightarrow H_2 \qquad \text{(Tafel)} \qquad (2)$$

$$H_2O + H_{ads} + e^- \longrightarrow H_2 + OH^- \quad \text{(Heyrovsky)} \quad (3)$$

Scheme S2. Hydrogen evolution reaction mechanism.

Figure S2. TEM images of samples with 1.11 g $Ni(NO_3)_2 \cdot 6H_2O$ calcinated at a) 700 °C, 1 h; b) 800 °C, 1 h; c) 900 °C, 1 h; d) 1000 °C, 1 h.
Figure S3. TEM images of samples with 1.11 g Ni(NO$_3$)$_2$·6H$_2$O calcinated at 700 ^{o}C with different holding time a) 1 h (NiO$_x$@NC-700), b) 2 h (NiO$_x$@BCNTs).

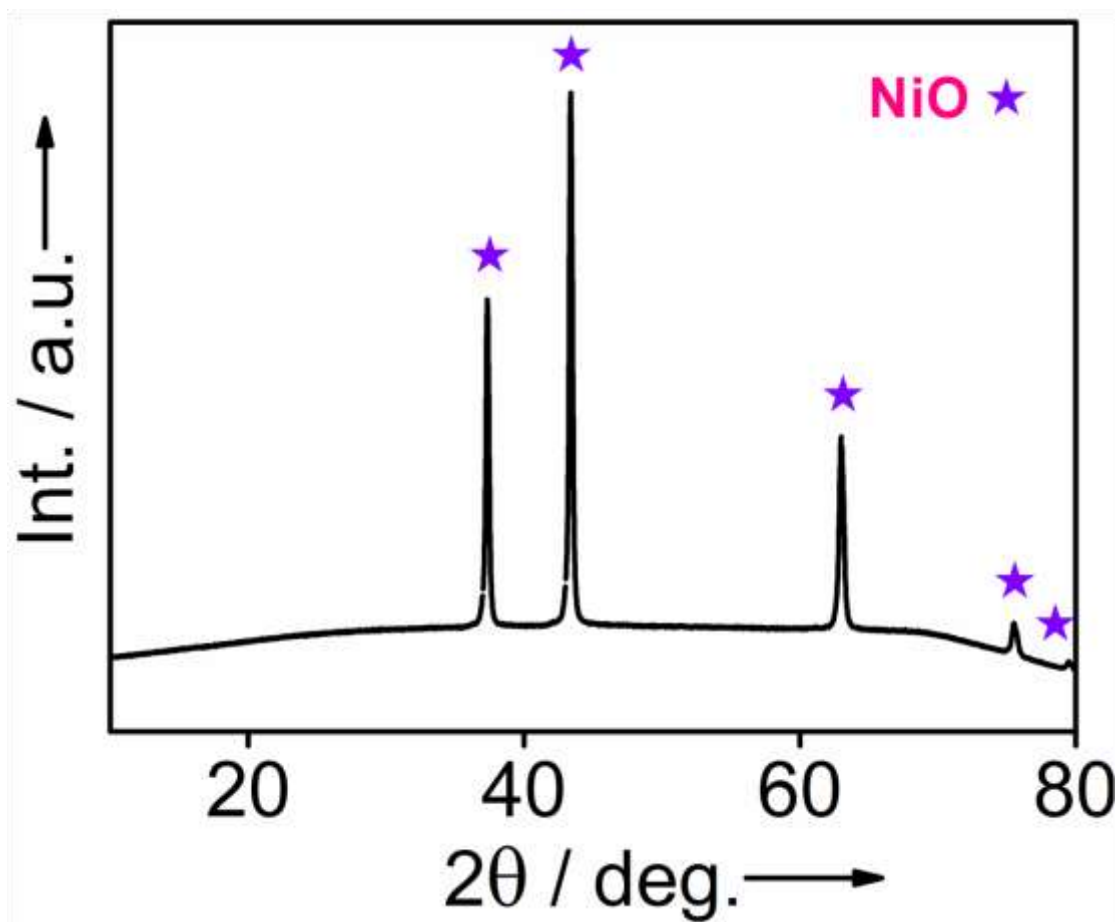

Figure S4. EDX elemental mapping of NiO$_x$@BCNTs.
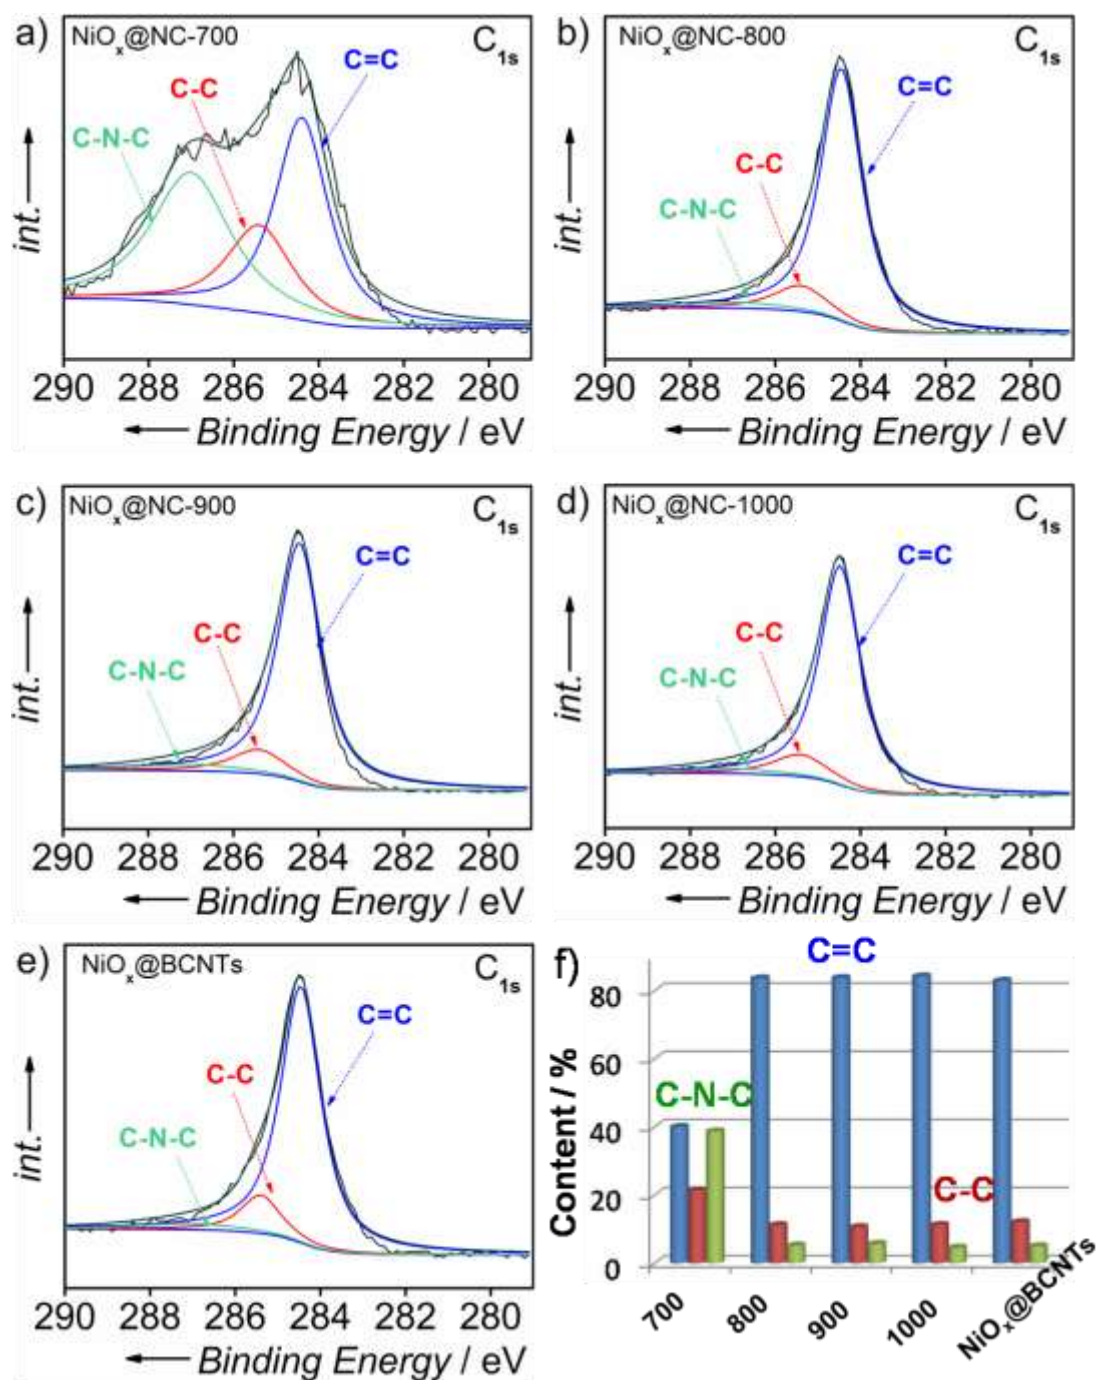

Figure S5. a, b, c, d, e) High-resolution C_{1s} XPS spectra of NiO_x@NC-700, NiO_x@NC-800, NiO_x@NC-900, NiO_x@NC-1000 and NiO_x@BCNTs. f) The content of the C=C, C-C and C-N-C species in products.
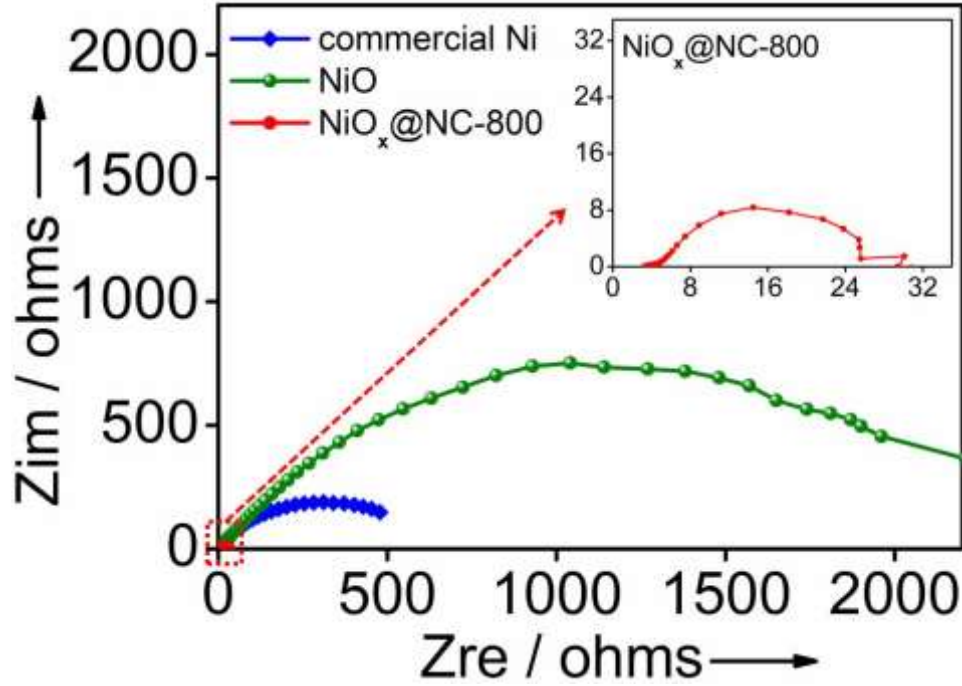

**Figure S6.** XRD of NiO calcinated at 800 ^{o}C for 1 h.

On the basis of XRD analysis (Figure S6), the characteristic peaks of contrast sample that directly calcinated $Ni(NO_3)_2 \cdot 6H_2O$ were assigned to NiO.

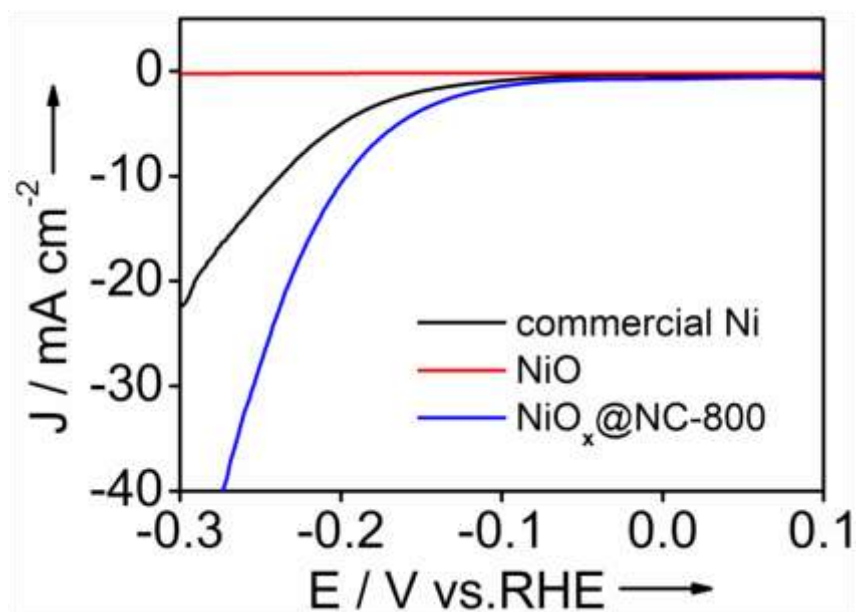

Figure S7. Polarization curves for control samples of commercial Ni, NiO and $NiO_x@NC-800$ in 1 M KOH.

Figure S8. EIS spectra of commercial Ni, NiO and NiO$_x$@NC-800. The insert showed the enlarged EIS spectra of NiO$_x$@NC-800.

Figure S9. a) EIS spectra of samples calcinated at 700 ^{o}C, 1 h, 700 ^{o}C, 2h (NiO$_x$@BCNTs); 800 ^{o}C, 1 h; 900 ^{o}C, 1 h; 1000 ^{o}C, 1 h. b) The enlarged EIS spectra of samples NiO$_x$@BCNTs; 800 ^{o}C, 1 h; 900 ^{o}C, 1 h; 1000 ^{o}C, 1 h.

Figure S10. Raman spectra of samples calcinated at different temperatures, 1.11 g $Ni(NO_3)_2 \cdot 6H_2O$, 1 h.

On the basis of Raman data (Figure S10), the graphitization degrees of catalysts were determined by obtaining the ratio of intensities of the two bands (i.e., I_D/I_G). The I_D/I_G ratio of NiO_x@NC-800 (I_D/I_G=1.27) is similar to that of NiO_x@NC-900 (I_D/I_G=1.28), and NiO_x@NC-1000 (I_D/I_G=1.21).

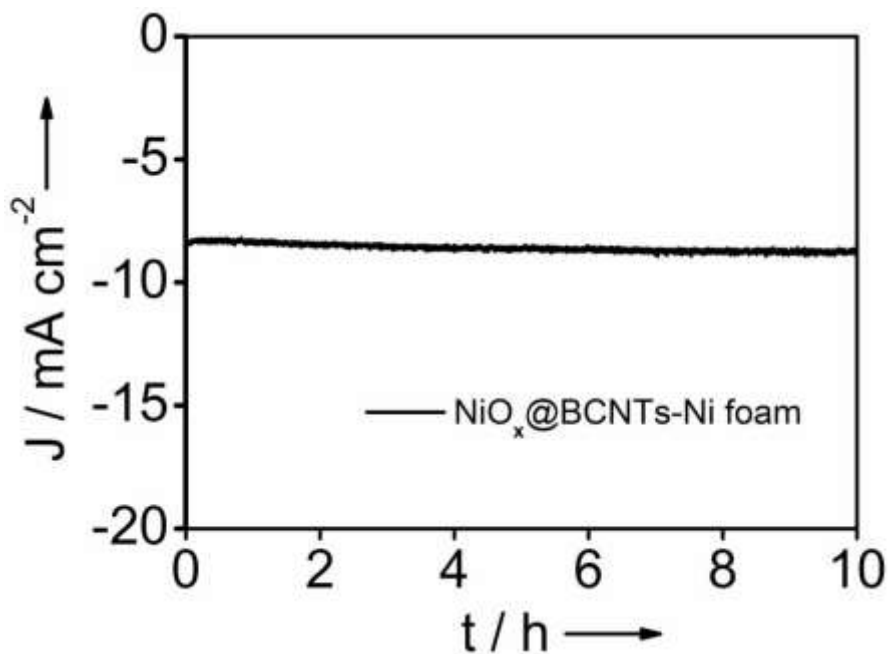

Figure S11. XRD of samples with 1.11 g $Ni(NO_3)_2 \cdot 6H_2O$ calcinated under different temperature for 1 h.

As shown in Figure S11, NiO_x@NC-700 only showed the diffraction peaks of graphite, owing to the formed Ni or NiO with lower crystallinity and smaller particle size under 700 °C.

Figure S12. Polarization curves of NiO_x@BCNTs in 1 M KOH with different loading mass.

Figure S13. Chronoamperometric response of NiO_x@BCNTs-Ni foam. The corresponding LSV data in Figure 3b was obtained after i-t test.

Computational section

Calculations were performed by using periodic, spin-polarized DFT as implemented in Vienna ab initio program package (VASP).[3-4] The electron-ion interactions were described by the projector augmented wave (PAW) method proposed by Blöchl[5] and implemented by Kresse.[6] PBE functional[7] was used as

exchange-correlation functional approximation and a plane wave basis set with an energy cutoff of 400 eV was chosen. A p (6×6) four-layer slab with (1 1 1) surface cleavaged was modeled as the active surface for the inherent Ni^0. As for the Ni/NiO interface model, a p (5×5) four-layer (1 1 1) NiO slab was embedded under one p (6×6) single layer (1 1 1) Ni^0 slab (see Figure S32). Only gamma k-point is used for the Brillouin zone sampling for these two models. A p (3×3) four-layer NiO slab with (100) surface was modeled for bulk NiO since this face is most stable.[8] A (2×2×1) k-point sampling is used for NiO model to ensure accuracy. Hubbard-U correction (DFT+U method)[9] was applied to improve the description of localized Ni d-electrons for Ni^0/NiO interface model. A value of U = 6.3 eV was set since this value is considered reasonable.[10-11] The bottom two layers were kept fixed during the structure optimization. Only gamma k-point is used for the Brillouin zone sampling. The periodic condition is employed along the x and y direction. The vacuum space along the z direction was set to be 15 Å. The relaxation is stopped when the force residue on the atom is smaller than 0.02 eV/Å. The hydrogen binding energy is defined using the equation:[12]

$$E^H_{atomic} = E_{H-slab} - E_{slab} - 0.5 \times E_{H2(g)}$$

where E^H_{atomic} is the binding energy of atomic hydrogen on the given slab, E_{H-slab} is the energy of the slab with one hydrogen adsorbed, E_{slab} is the energy of the slab in a vacuum, and $E_{H2(g)}$ is the energy of hydrogen in the gas phase.
Figure S32. Hydrogen binding on (a) inherent Ni^0 (111); (b) Ni/NiO (111) interface; (c) Ni site of NiO(100); (d) O site of NiO (100). Cyan: nickel; red: oxygen; white: hydrogen.
