RECEIVED DATE (will be automatically inserted after manuscript is accepted).

For the reaction of electrophile **4a** with **MB**, the structure of the corresponding acid $\mathbf{N}\text{-E}^\Theta\text{H}^+$ relates to that of $\mathbf{H}^+\mathbf{N}\text{-E}$ as well as $\mathbf{H}^+\mathbf{N}^\Theta$. However, the pK_a of $\mathbf{N}\text{-E}^\Theta\text{H}^+$ should be smaller than that of $\mathbf{E}^\Theta\mathbf{H}^+$. For instance, the phenyl substitution increases the acid strength of 2-phenyl barbituric acid ($pK_a = 2.54$ in water)^[1] compared to barbituric acid ($pK_a = 3.9$ in water).^[2] That modification would have consequence on actual K -values (Scheme 10). K is estimated to be in the range between 100 or 1000 Lmol^{-1} for the **4a/MB** system. Accordingly, an incomplete conversion of **4a** with **MB** is experimentally found (see Figure 2, left part, as example). The equilibrium constants for 1:1 stoichiometry have been determined for those combinations which show incomplete conversion taking into account the concentration of the electrophile which is measured after reaching the equilibrium state after about one second (for example see Figure 2, left part). Results of the equilibrium measurements for electrophile **4a** are compiled in Table S1. The magnitude of the equilibrium constant for each combination is confirmed by independently determined K -values which are derived from the k_2/k_{-1} ratio. k_{-1} can be estimated from ordinate intercept according to Figure 2, right part. The agreement of both K -values for the **4a/MB** system is coherent. For the **4a/ESB** it is not possible to calculate reasonable K values if assuming the 1:1 equilibrium from the concentration measurements due to K is a function of **ESB** concentration (see Table S1). Using constant anion, for electrophile **3a** the K -values are significantly greater than for **4a** which is expected. The equilibrium constants calculation also shows that the consideration above, K is about 10^2 to 10^3 Lmol^{-1} for the **4a/MB** system, has been confirmed. Thus, the equilibrium constants K of the $\mathbf{E} + \mathbf{N}^\Theta$ combinations can be speculatively estimated by $pK \approx \Delta pK_a + 3$, if ΔpK_a is simply obtained from the pK_a -values of the corresponding acids of the reactants (see discussion of Table 3). The number 3 comes from the pK_a -difference of barbituric acid derivatives and 2-phenylbarbituric acid which is used to adapt the molecular structure change after the C–C-bond formation reaction.

From the incomplete conversion, the equilibrium constants ($K_{\text{conversion}}$) and the rate constants of the back reaction ($k_{-1,\text{conversion}}$) were calculated and compared with rate constants determined by the axis interception ($k_{-1,\text{kinetic}}$) and the thereby calculated equilibrium constant (K_{kinetic}) (Table S1).

Indeed, the k_{PT}/k_{-1} -value for electrophile **6** type/barbiturate combinations is always less than 1 (Table 4). But the values are not that small as found for electrophile **5**, which means that the extreme scenario considered according to eq. 4 is not completely accomplished for these nucleophile/electrophile combination. For instance, the faster the C–C-bond formation occurs for the electrophiles of type **6**, the faster also the proton transfer reaction takes place as indicated by the k_{PT}/k_{-1} ratio. The deviation of $k_{2,\text{calculated}}$ in relation to $k_{2,\text{obs}}$ increases steadily with increasing ΔG^\ddagger (theoretically calculated). In the same way the rate constant for the proton transfer should decrease significantly. Therefore, two interfering effects, a low concentration of ${}^\Theta\text{N}\text{-E}$ and a depressed proton transfer rate, may be responsible for the deviating kinetics. The subsequent proton transfer step should take place very fast for the electrophiles of type **6** if the C–C-band formation is irreversible

Table S1 Equilibrium constant (K) calculated by the incomplete conversion of nucleophile-electrophile reactions (left columns) and from the axis interception of the plots $k_{2,\text{obs}}/[\text{N}^\Theta]$ (right column).

Kinetic experiments

General Procedure:

All reactions were performed in dry DMSO (< 0.005% water) from Acros Organics at 20 °C. Fast reactions ($\tau_{1/2} < 100$ s) were measured at stopped-flow spectrophotometer system Hi-Tech SF-61DX2, for slower reactions a UV/vis spectrometer MCS 400 from the Carl Zeiss Jena GmbH with optical immersion probe were used. The rate constants k_{obs} (s $^{-1}$) were obtained by fitting the function $A_t = A_0 \cdot \exp(-k_{\text{obs}} \cdot t) + C$ at the plot of the electrophil absorption over the time. The barbiturate anions were used as potassium salts.

The given errors were determined by RGP-function with Microsoft Exel 2013. The maximal error of $\log k_2$ is ± 0.02 .

Kinetics of a Nucleophile electrophil reaction with a subsequent proton transfer:

Independently of the real mechanism of the PT-reaction, this process is considered as first-order-reaction with respect to its stoichiometry. The suggested scenario, which includes the equilibrium of the C–C-bond formation and the subsequent PT-reaction, is shown in eq. S1

The rate law for the Bodenstein approximation (steady state of the initially formed adduct: $\text{N}-\text{E}^\ominus$) is given in eq. S2.

$$d[\text{N}-\text{E}^\ominus]/dt = k_2[\text{E}][\text{N}^\ominus] - k_{-1}[\text{N}-\text{E}^\ominus] - k_{PT}[\text{N}-\text{E}^\ominus] + k_{-PT}[{}^\ominus\text{N}-\text{E}] = 0 \quad (\text{S2})$$

If the equilibrium between $\text{N}-\text{E}^\ominus$ and ${}^\ominus\text{N}-\text{E}$ lies on the side of ${}^\ominus\text{N}-\text{E}$, than it could be stated that $k_{PT}[\text{N}-\text{E}^\ominus] \gg k_{-PT}[{}^\ominus\text{N}-\text{E}]$. From this assumption eq. S3 could be formulated.

$$d[\text{N}-\text{E}^\ominus]/dt = k_2[\text{E}][\text{N}^\ominus] - k_{-1}[\text{N}-\text{E}^\ominus] - k_{PT}[\text{N}-\text{E}^\ominus] = 0 \quad (\text{S3})$$

$$\text{This means } [\text{N}-\text{E}^\ominus] = k_2[\text{E}][\text{N}^\ominus]/(k_{-1} + k_{PT}) \quad (\text{S4})$$

For negligible concentrations of the intermediate $[\text{N}-\text{E}^\ominus]$, the rate of formation of the final product $[{}^\ominus\text{N}-\text{E}]$ equals the rate of consumption of the electrophile, as shown in eq. S5, where k_{-PT} is neglected because the conversion of $\text{N}-\text{E}^\ominus$ into ${}^\ominus\text{N}-\text{E}$ is quantitative.

$$-d[\text{E}]/dt = d[{}^\ominus\text{N}-\text{E}]/dt = k_{PT}[\text{N}-\text{E}^\ominus] \quad (\text{S5})$$

Substitution of eq. S4 into eq. S5 yields eq. S6

$$d[\text{E}]/dt = -k_2[\text{E}][\text{N}^\ominus] (k_{PT}/(k_{PT} + k_{-1})) \quad (\text{S6})$$

For $k_{PT} \gg k_{-1}$, eq. S6 simplifies to eq. S7

$$d[\text{E}]/dt = -k_2[\text{E}][\text{N}^\ominus] \quad (\text{S7})$$

and for $k_{PT} \ll k_{-1}$, eq. S6 transforms to eq. S8

$$d[\text{E}]/dt = -k_2[\text{E}][\text{N}^\ominus] (k_{PT}/k_{-1}) = -k_{PT}K[\text{E}][\text{N}^\ominus] = k_{app}[\text{E}][\text{N}^\ominus] \quad (\text{S8})$$

with $K = k_2/k_{-1}$

Table S2. Corresponding acids of the investigated *Michael*-acceptor electrophiles and their pK_a -values in DMSO.

corresponding Acid		pK_a (DMSO)
	Meldrum's Acid	7.3 ^[3]
	Indandione	7.8 ^[4] DMSO/H ₂ O (90:10)
	Barbituric Acid	8.4 ^[3]
	Malononitrile	11.0 ^[3]
	2,6-Di- <i>tert</i> -butylphenol	16.8 ^[3]

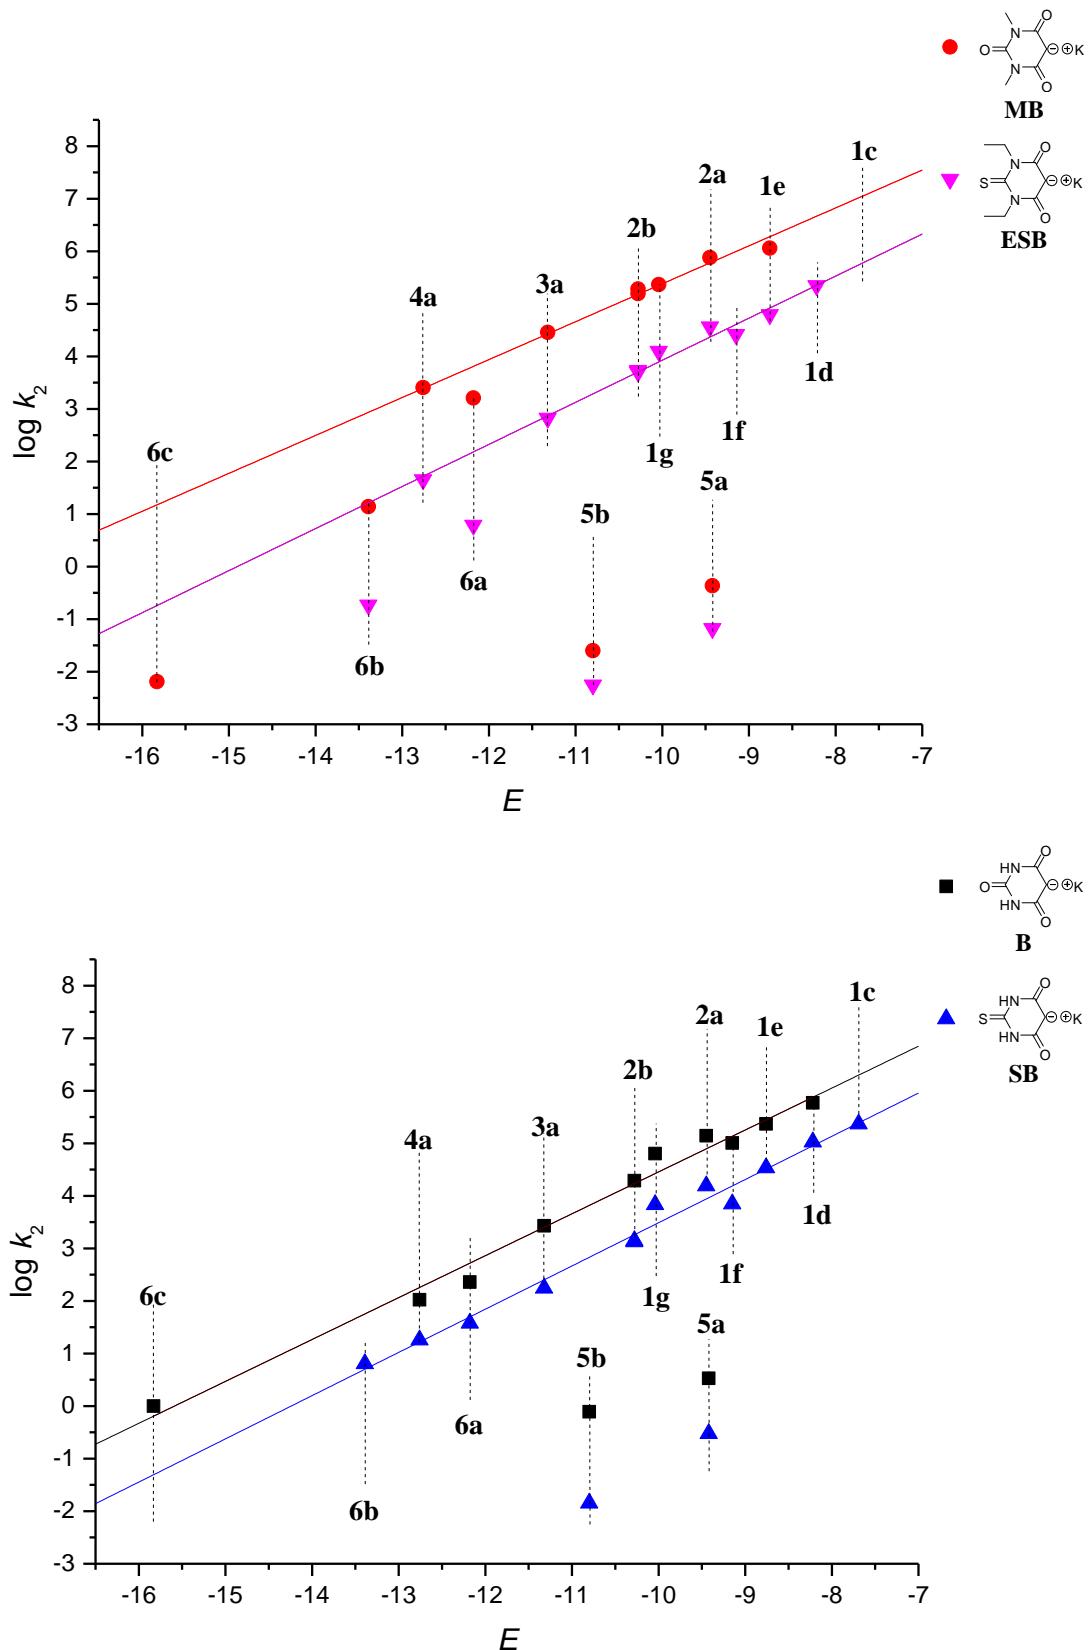

Figure S1. Comparison of alkylated oxo- and thiobarbituric anions (**MB**, **ESB**) at the top and unalkylated oxo- and thiobarbituric anions (**B**, **SB**) at the bottom, for better visualization of the slower rate constants (k_2) of thiobarbiturate anions.

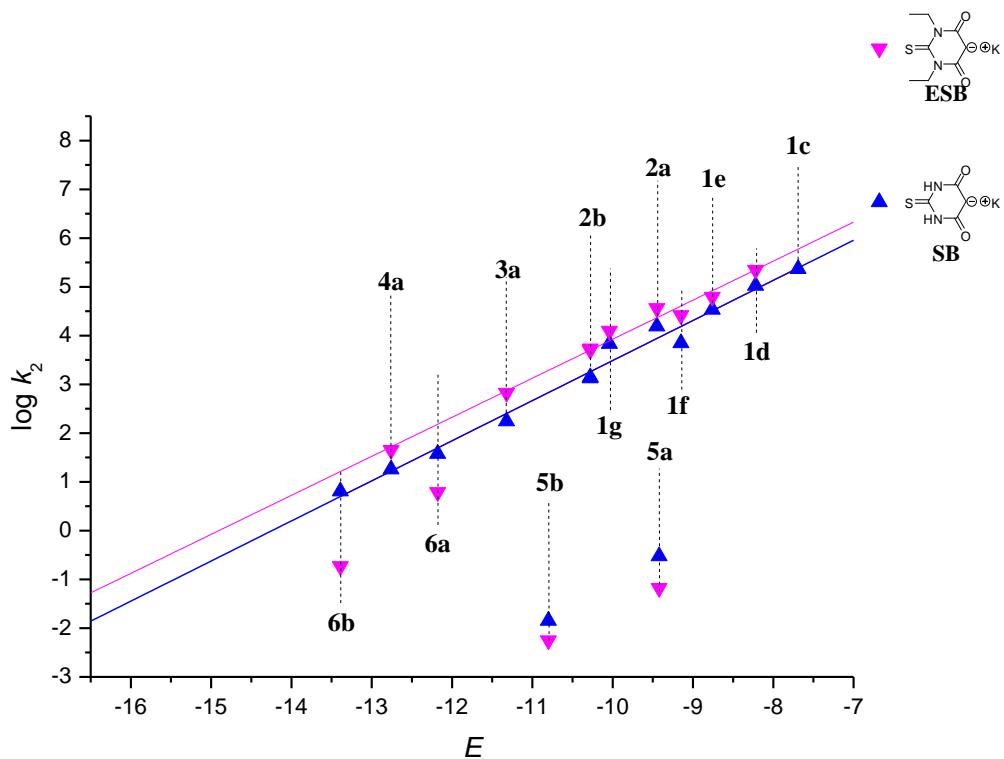

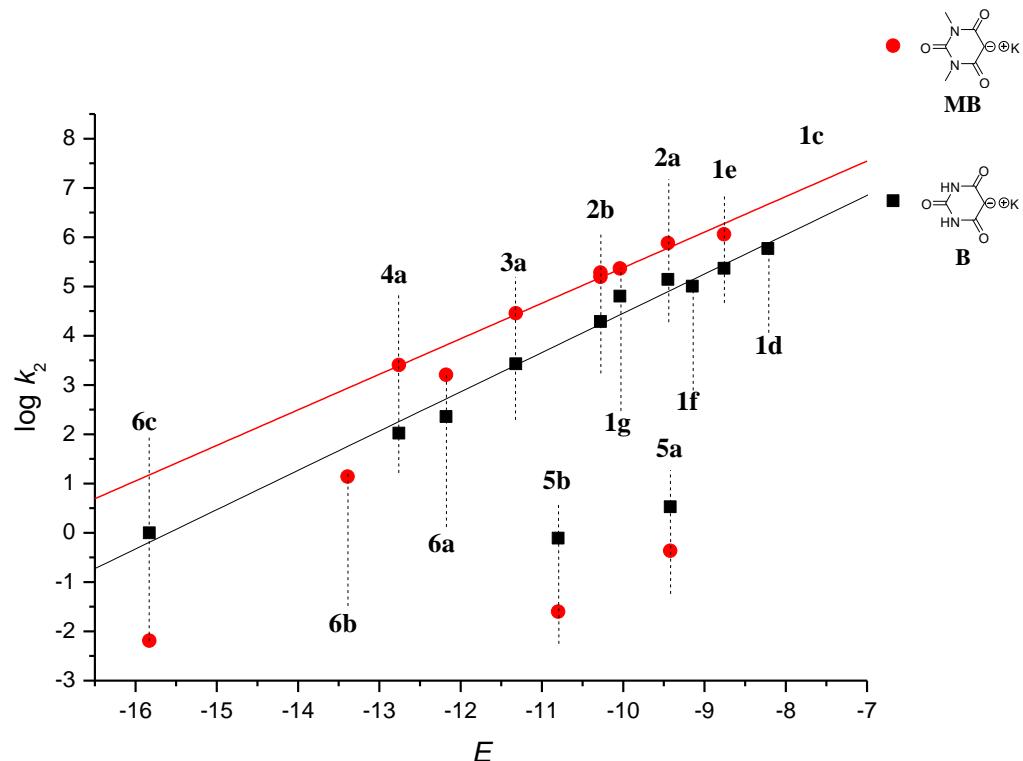

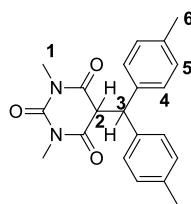

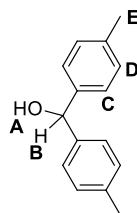

Figure S2. Comparison of alkylated and unalkylated oxobarbituric anions (**B**, **MB**) at the top and alkylated and unalkylated thiobarbituric anions (**SB**, **ESB**) at the bottom, for better visualization of the faster rate constants (k_2) through alkylation of barbiturate anions. Notable is the inverse substituent effect for the kinetics of electrophiles 5a and 5b, caused by the invers substituent effects on the proton transfer reaction.

NMR-Spectra – Product studies

Quantum chemical calculations

1. Investigation setting

For the quantum chemical investigation of the ambident reactivity of **B** and **MB**, the (barbiturate)C(5)–C(electrophile) axis and the (barbiturate)O–C(electrophile) axis are chosen as reaction coordinates for *C*- and *O*-alkylation modeling, respectively. The solvent effects for DMSO are included by the COSMO solvation model with $\epsilon = 48$.

All reactions are modeled by performing relaxed scans along the relevant reaction coordinates. A step width of 0.02 Å is applied to carefully find the corresponding transition state structures. These structures are further utilized for single-point calculations. The identified minima structures from the relaxed scans are further optimized without constraints. Then, single-point calculations are performed using optimized molecular structures.

2. Relative energies and relative Gibbs energies

Table S3. Single-point relative energies and relative Gibbs energies for the optimized molecular and transition state structures for the alkylation of **B** and **MB** with **1a**, **2a,b**, **4a**, **5a-c** and **6a** at PW6B95-D3/TZVP/COSMO ($\epsilon = 48$) level of theory. The relative energies include ZPVE, which was scaled by a factor $f = 0.9914$. The relative Gibbs energies are calculated for a reaction temperature of 20 °C (293.15 K). The lowest dispersion complex is set to zero. All units are given in kJ/mol. (For further information see computational details.)

Table S5. Calculated values for chemical potential (μ), energy (E), entropy (S) and enthalpy (H) and ZPVE for the optimized molecular and transition state structures for the alkylation of **B** and **MB** with **1a**, **2a,b**, **4a**, **5a-c** and **6a** at BP86-D3/TZVP/COSMO ($\epsilon = 48$) level of theory. ZPVE was scaled by a factor $f = 0.9914$. All values are calculated for a reaction temperature of 20 °C (293.15 K). (For further information see computational details.)

BP86-D3/TZVP/COSMO ($\epsilon = 48$)
